

Chatbot in 7 Days

How to use NNOD to create chatbot in a week

Development Diary: February 22, 2018 - February 28, 2018

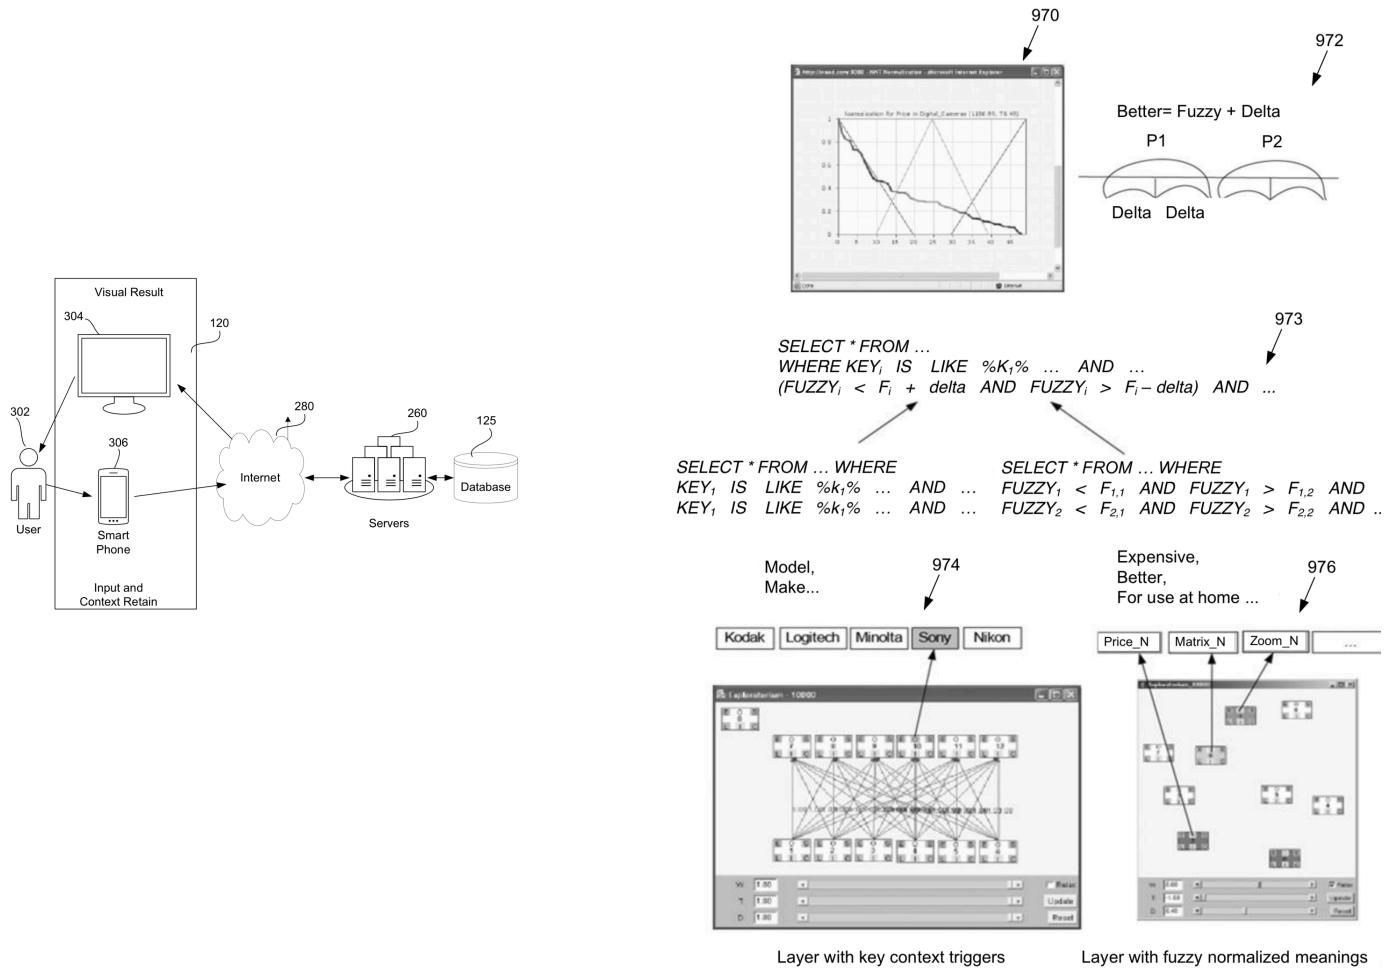

Best Buy

Introduction

This is an example how to create a chatbot or virtual assistant, capable to run in multi-channel environment (chat, voice, PC, smartphone, TV, interactive kiosks) by using [NNOD SDK](#) and the very basic development resources. I want to show how simple can be the process of building interactive contextual search assistant when using neural networks based [Expert System](#).

By using [Best Buy website](#) and its [Development API](#) I will build interactive assistant (chatbot) in [one man-week](#) and keep daily records of the development process:

Day 1

Project preparation. Agile vs Waterfall. Data Source.

Since this is a one man project I have to find the best way to plan and manage the progress towards final product. Because I will be the only one working on it during the next 7 days, all traditional function: management, architectural design, UI, front and back programming, QA and few others, will be implemented inside the one man's mind.

Personally, I prefer the [Waterfall model](#), but considering that I have minimum possible resources allocated to this project, I've decided to use [Agile](#). The "virtual manager", "virtual architect", etc. will "virtually" interact in my mind to deliver the result of the real team collaboration. As at many projects in real life, I will have my board to put the virtual notes, similar to notes I have in front on my iMac:

Learning Best Buy API.

The very first step in this project is to get registered on BestBuy Development site and obtaining API key. To get it I went to <https://developer.bestbuy.com> and felt application form to obtain API Key. This Key required sending requests to Best Buy's database.

The next step is to learn and experiment with Best Buy API (BB API). It takes some time to understand the structure, components, and formats of API. The important tool in this process is the Query Builder - <http://bestbuyapis.github.io/bby-query-builder/#/productSearch>. I spent the most of my time to understand the structure of JSON queries and responds.

For example, informal request - "Show me cameras around \$200 with the best reviews" can be reformulated in Query Builder's [formal request](#):

The screenshot shows the Best Buy API Query Builder interface. On the left, there are three main sections: 1) Search for Products, which includes dropdowns for category (Digital Cameras), keyword (Enter Keyword(s)), price range (Regular Price: > 100, < 300), and review average (>= 4). 2) Build Your Response, which includes checkboxes for product attributes (Name, Regular Price, Image, URL, Customer Review Average) and facets (Regular Price: Number: 50). 3) Pagination, which includes dropdowns for results per page (100) and page number (1). On the right, the URL Breakdown section displays the constructed URL and its components:

```
baseURL : https://api.bestbuy.com/v1/products
categoryId : (categoryPath.id=abcat0401000)
attribute :
(regularPrice>100&regularPrice<300&customerReviewAverage>=4)
apiKey : ?apiKey=7ksBhjryZ5hxofJSEk2VBO7u
sortOptions : &sort=customerReviewAverage.dsc
showOptions :
&show=name,regularPrice,image,url,customerReviewAverage
pagination : pageSize=100
facets : &facet=regularPrice,50
responseFormat : &format=json
```

Below this is the Complete URL:

```
#request: [copy]
https://api.bestbuy.com/v1/products(regularPrice>100&regularPrice<300&customerReviewAverage>=4&(categoryPath.id=abcat0401000))?
apiKey=7ksBhjryZ5hxofJSEk2VBO7u&sort=customerReviewAverage.dsc&show=name,regularPrice,image,url,customerReviewAverage&facet=regularPrice,50&pageSize=100&format=json
```

And the response preview:

```
{
  "from": 1,
  "to": 40,
  "currentPage": 1,
  "total": 40,
  "totalPages": 1,
  "queryTime": "0.123",
  "totalTime": "0.243",
  "partial": false,
  "canonicalUrl":
  "/v1/products(regularPrice>100&regularPrice<300&customerReviewAverage>=4&(categoryPath.id=abcat0401000))?
  show=name,regularPrice,image,url,customerReviewAverage&sort=customerReviewAverage.dsc&pageSize=100&format=json&facet=regularPrice,50&apiKey=7ksBhjryZ5hxofJSEk2VBO7u",
  "products": [
    {
      "name": "Panasonic - LUMIX DMC-TS30 16.1-Megapixel Waterproof Digital Camera - Blue",
      "regularPrice": 179.99,
      "image":
      "https://img.bbystatic.com/BestBuy_US/images/products/4032/4032159_ra.jpg"
    }
  ]
}
```

At the same time, on the background, I already had started architectural design and preparation for the presentation of responses in more dynamic visual form.

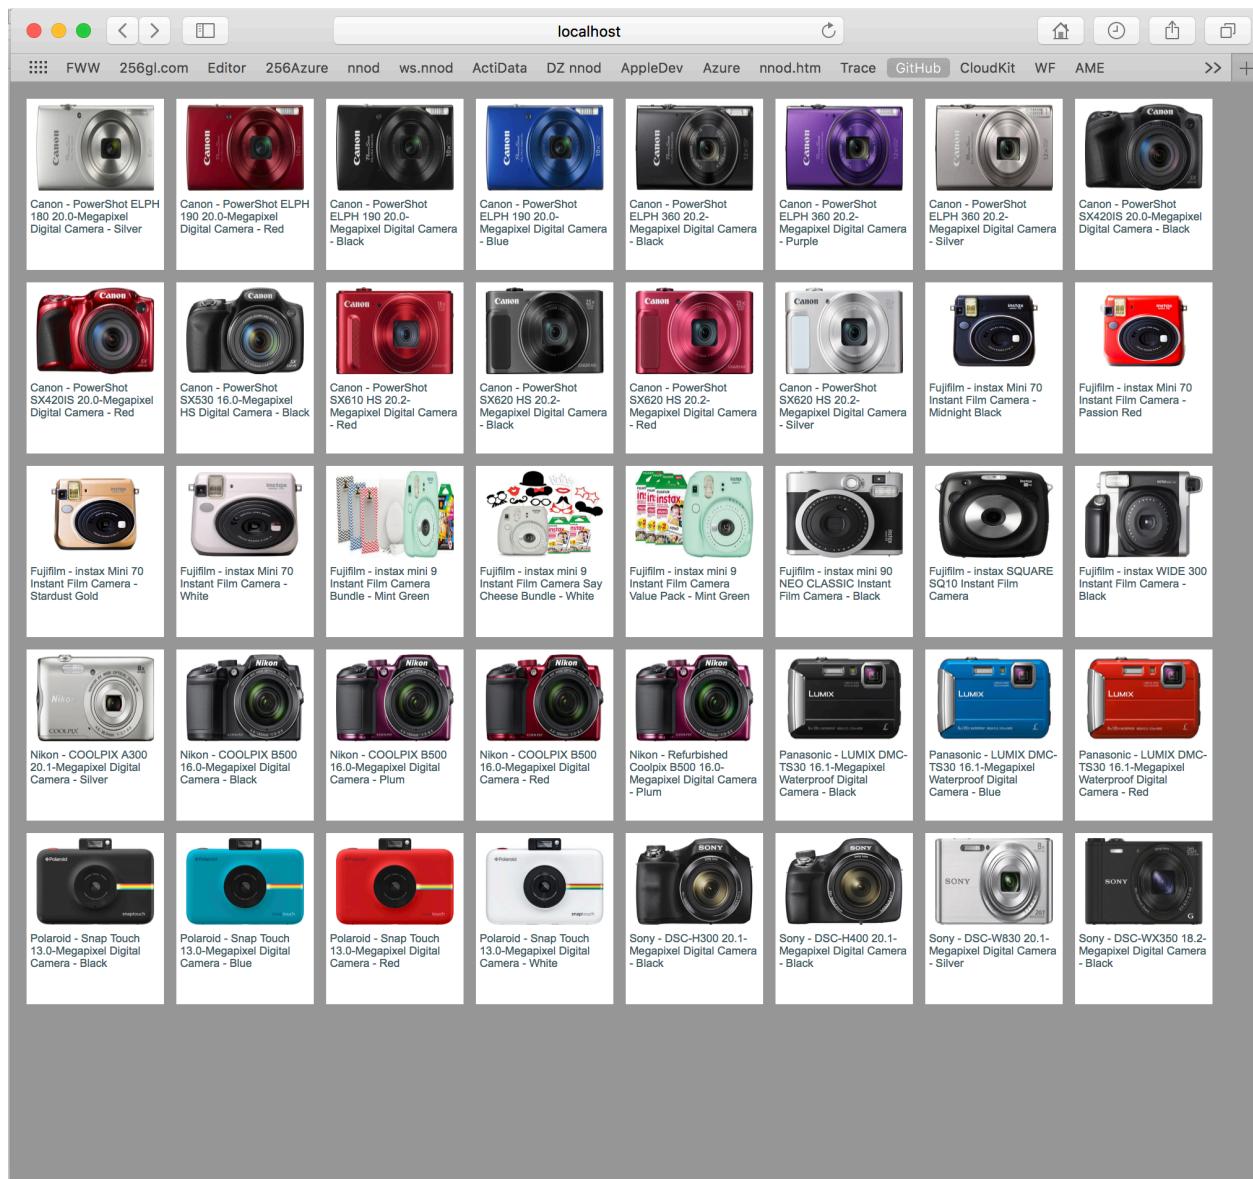

To make this solution generic as possible, I am using basic Web Server and building interactive chat page using only standard JavaScript.

The NNOD API published as Open Source under GNU license in [GitHub](#), and I had added this solution into the same GitHub repository under [bestbuy](#) directory.

Local Development Environment.

I am building chatbot on iMac, but there are no any differences in the implementation for Windows. I am using Apache Web Server on Mac and IIS Web Server on Windows.

To make the very first call to [BB API](#) I have started with simple PHP request (potentially one of the next versions may require server integration):

```

<body style="background-color:#999999;">
<?php
$url = "https://api.bestbuy.com/v1/
products(customerReviewAverage%3E=4&regularPrice%3E150&regularPrice%3C250&(ca
tegoryPath.id=abcat0401000))?
apiKey=xxxxxx&sort=name.asc&show=manufacturer.name,image,url,regularPrice&fac
et=regularPrice,50&pageSize=100&format=json";
$data = file_get_contents($url);
$json = json_decode($data, true);
$array = $json[ "products" ];
$db_counter = 1;
foreach ($array as $obj) {
    $db_counter = $db_counter + 1;
    echo "<div class=\"thumbnail_wrapper\"><table cellspacing=\"0\" "
cellpadding="0"><tr>\n" .
    "<td id=\"td_thumbnail_\" . $db_counter . \"\"
class=\"td_thumbnail_image\">\n" .
    "<a href=\"#\"><img src=\"\" . $obj[ 'image' ] . "\" height='70' width='95' \" .
    "\" onclick=\"javascript:openThumbnailLink('\" . $obj[ 'url' ] . '\"); return
false;\"></a></td>\n" .
    "</tr><tr><td id=\"td_thumtitle_\" . db_counter . \"\"
class=\"td_thumbnail_title\">\n" . " " . $obj[ 'name' ] . "\n" .
    "</td></tr></table></div> \n\n";
}
?>
</body>

```

The result:

Day 1 outcome.

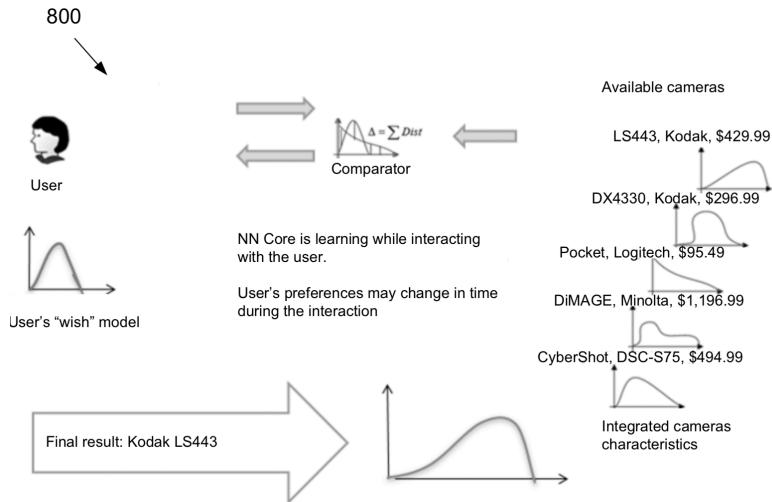

- BB API Key obtained and I have full access to BB database.
- The very first Web Page with implementation of requests to BB API built.
- Clear understanding of BB API now allows starting building Linguistic model for interactive search.

Day 2

Architectural/Marketing.

What is the value of my chatbot? - This is one of the most important questions I must answer before and during the process of chatbot development. What are the criteria I can establish to evaluate the advantages of this ChatBot compare to the others similar solutions? I decided to use cost of service and satisfaction of the customer (user) request as my criteria.

When user wants to buy some product or service, he/she needs to get enough information to make the final decision. And before the very last moment when sale is completed, the information for decision making would be collected from many sources: the Web, personal notes, social networks and finally a human experts are the networks of participants in interactive process of selecting the best product from many available on the market.

Basically, the process includes collecting data from different sources; compare the results and repeating the process until the threshold level for the decision has reached.

The cost of this process has two components: user (customer) cost, which includes time and potential lost (if the item is wrong, or the same item can be purchased for lower price); and cost of sale for the companies that sell products through the multi-channels (the cost of service and cost of possibility of losing client if he/she decided to switch to different provider).

I am using Best Buy Web site as one of the sources for measuring the success. The Criteria #1 will be based on the time required for the user to find enough information about product and make decision to move forward and complete the purchase (visit Best Buy store or to switch to another retailer).

PHP -> JavaScript.

Even PHP is very popular and widely supported language; wherever it is possible I am using JavaScript for the reason scalability and support minimization. If my solution is fully JavaScript based it will not require any external server support except BB API, which mean that I will automatically solve the problem of scalability.

Changing PHP to JavaScript is relatively easy:

```
<!DOCTYPE HTML>
<html>
<head>
<meta http-equiv="X-UA-Compatible" content="IE=edge" />
<meta http-equiv="content-type" content="text/html; charset=UTF-8" />
<meta name="apple-mobile-web-app-capable" content="yes" />
<meta name="apple-mobile-web-app-status-bar-style" content="black" />
<meta name="viewport" content="minimum-scale=1.0, maximum-scale=5.0, user-scalable=yes, initial-scale=1.0" />
<meta name="viewport" content="user-scalable=yes">

<title>256gl NNOD</title>
<link rel="stylesheet" type="text/css" href="style.css" />
<script type="text/javascript">
    function openThumbnailLink(url) {
        window.open(url, "_blank", "toolbar=no, scrollbars=yes, resizable=yes,
top=10, left=10, width=800, height=800");
        return true;
    };
</script>
</head>
<body style="background-color:#999999;">
<div id="demo"></div>
<script>
    var xmlhttp = new XMLHttpRequest();
    xmlhttp.onreadystatechange = function() {
        if (this.readyState == 4 && this.status == 200) {
            var myObj = JSON.parse(this.responseText);
            var result = myObj.products;
            var x = "";
            for (i in result) {
                x = x + "<div class=\"thumbnail_wrapper\"><table cellspacing=\"0\""
cellpadding="0"><tr>\n" +
                "<td id=\"td_thumbnail_" + i + "\" class=\"td_thumbnail_image\">\n" +

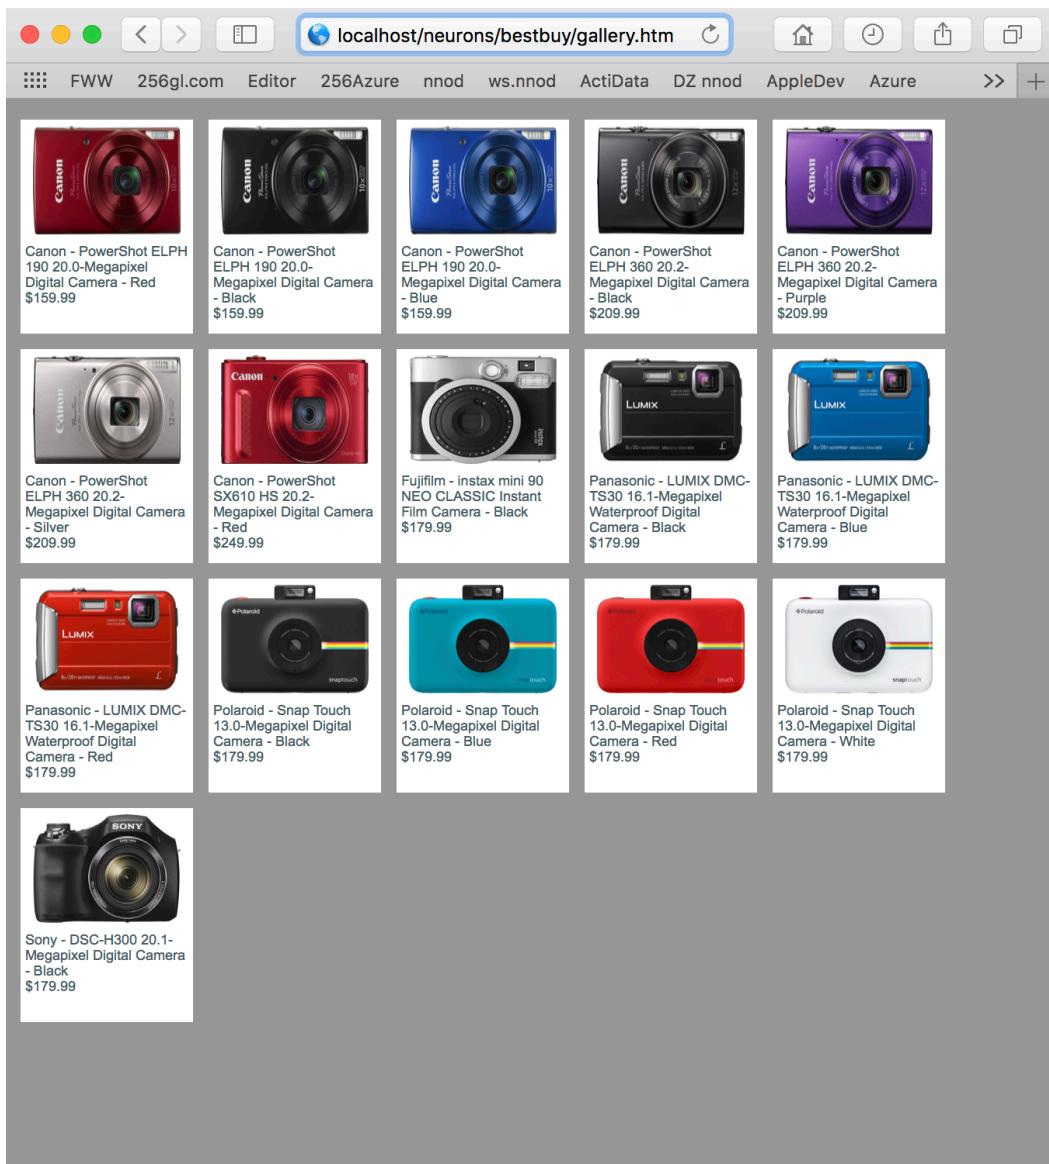

```

```

    "<a href=\"#\\"><img src=\"\" + result[i].image + \" height='70' width='95' \" +
    "\ onclick=\"javascript:openThumbnailLink('" + result[i].url + "'); return false;"></a></td>\n" +
    "</tr><tr><td id=\"td_thumtitle_" + i + "\"
    class=\"td_thumbnail_title\">\n" + " " + result[i].name + "<br>$" +
    result[i].regularPrice + "\n" +
    "</td></tr></table></div> \n\n";
}
document.getElementById("demo").innerHTML = x;
}
};

url = "https://api.bestbuy.com/v1/
products(customerReviewAverage%3E=4&regularPrice%3E150&regularPrice%3C250&(categoryPath.id=abcat0401000))?
apiKey=xxxxxxxx&sort=name.asc&show=manufacturer.name,image,url,regularPrice&facet=regularPrice,50&pageSize=100&format=json";
xmlhttp.open("GET", url, true);
xmlhttp.send();
</script>
</body>
</html>

```

Parameters in HTTP Request.

BB API allows sending request only with the certain relatively restricted set of parameters. Currently it's allowing me only to request products defined by: Category, CustomerReview, Manufacturer, Color and Price. The formal request to BB Database can be built only with combination of these parameters.

To load or reload gallery page I will use HTTP Get method:

[http://localhost/neurons/bestbuy/gallery.html?
color=silver&manufacturer=apple&customerReviewAverage=3&price=1500](http://localhost/neurons/bestbuy/gallery.html?color=silver&manufacturer=apple&customerReviewAverage=3&price=1500)

The presentation layer (gallery.html) has the arguments parser and few logical adjustments.

It is almost impossible in user's informal request define price as an exact number, so I am converting the Price into the range and if no exact criteria provided, the price for the request calculates as:

```
regularPrice_gt = price - Math.round(price / 4)
regularPrice_lt = price + Math.round(price / 4)
price >= regularPrice_gt && price <= regularPrice_lt
```

The whole arguments parsing for the page is following:

```
var api_key = "7ksBhjryZ5hxofJSEk2VB07u";
var baseURL = "https://api.bestbuy.com/v1/products";
var categoryId = get_arguments["categoryId"];
if (categoryId === undefined) categoryId = "abcat0502000";

// abcat0502000 - Laptops
// abcat0501000 - Computers
// abcat0401000 - Cameras
// pcmcat209400050001 - phones
// abcat0204000 - Hesad phones
// pcmcat241600050001 - Home Audio
// pcmcat254000050002 - Home Automation
// pcmcat209000050006 - iPads
// abcat0904000 - Ovens
// abcat0901000 - Refrigerators
// abcat0101000 - TVs
// abcat0910000 - Washers
// pcmcat310200050004 -Speakers

var customerReviewAverage = get_arguments["customerReviewAverage"];
if (customerReviewAverage === undefined)
{
    customerReviewAverage = "";
```

```

} else
{
    customerReviewAverage = customerReviewAverage - 0.1
    customerReviewAverage = "&customerReviewAverage>=" + customerReviewAverage;
}
var manufacturer = get_arguments["manufacturer"];
if (manufacturer === undefined)
{
    manufacturer = "";
}
else
{
    manufacturer = "&manufacturer=" + manufacturer;
}
var color = get_arguments["color"];
if (color === undefined)
{
    color = "";
}
else
{
    color = "&color=" + color;
}
var regularPrice_gt = 0;
var regularPrice_lt = 100000;
var price = get_arguments["price"];
if (price === undefined || price === "")
{
    price = "regularPrice>=" + regularPrice_gt +
        "&regularPrice<=" + regularPrice_lt;
}
else
{
    regularPrice_gt = Math.round(price) - Math.round(price / 4);
    regularPrice_lt = Math.round(price) + Math.round(price / 4);
    price = "regularPrice>=" + regularPrice_gt +
        "&regularPrice<=" + regularPrice_lt;
}
var url = baseURL + "(" + price + customerReviewAverage + manufacturer +
color +
"&(categoryPath.id=" + categoryId + "))" +
"?apiKey=" + api_key +
"&sort=name.asc&show=manufacturer,name,image,url,regularPrice&facet=regularPr
ice,50&pageSize=100&format=json";

```

With this update I can now request different category of products and update the search criteria.

Day 3

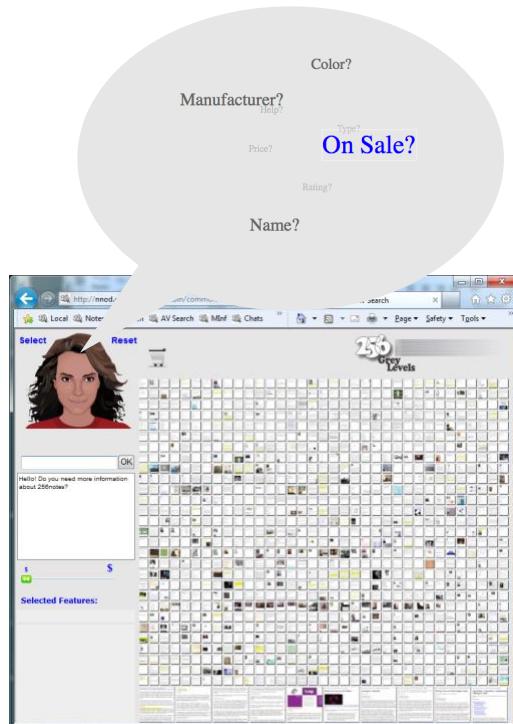

Domain of Definition, Map Informal Requests into Formal Queries.

One of the most important steps in chatbot design is the clear understanding of “[Domain of a Function](#)”. The informal human request needs to be mapped into the formal query. The goal of our design is to map practically endless variety of informal request into the limited set of the allowed parameters in query, which results with limited number of items from the database. In our case, Best Buy API is limited by Product, Stores, Categories and Recommendation types of queries. Understanding of this limitation makes development significantly simpler.

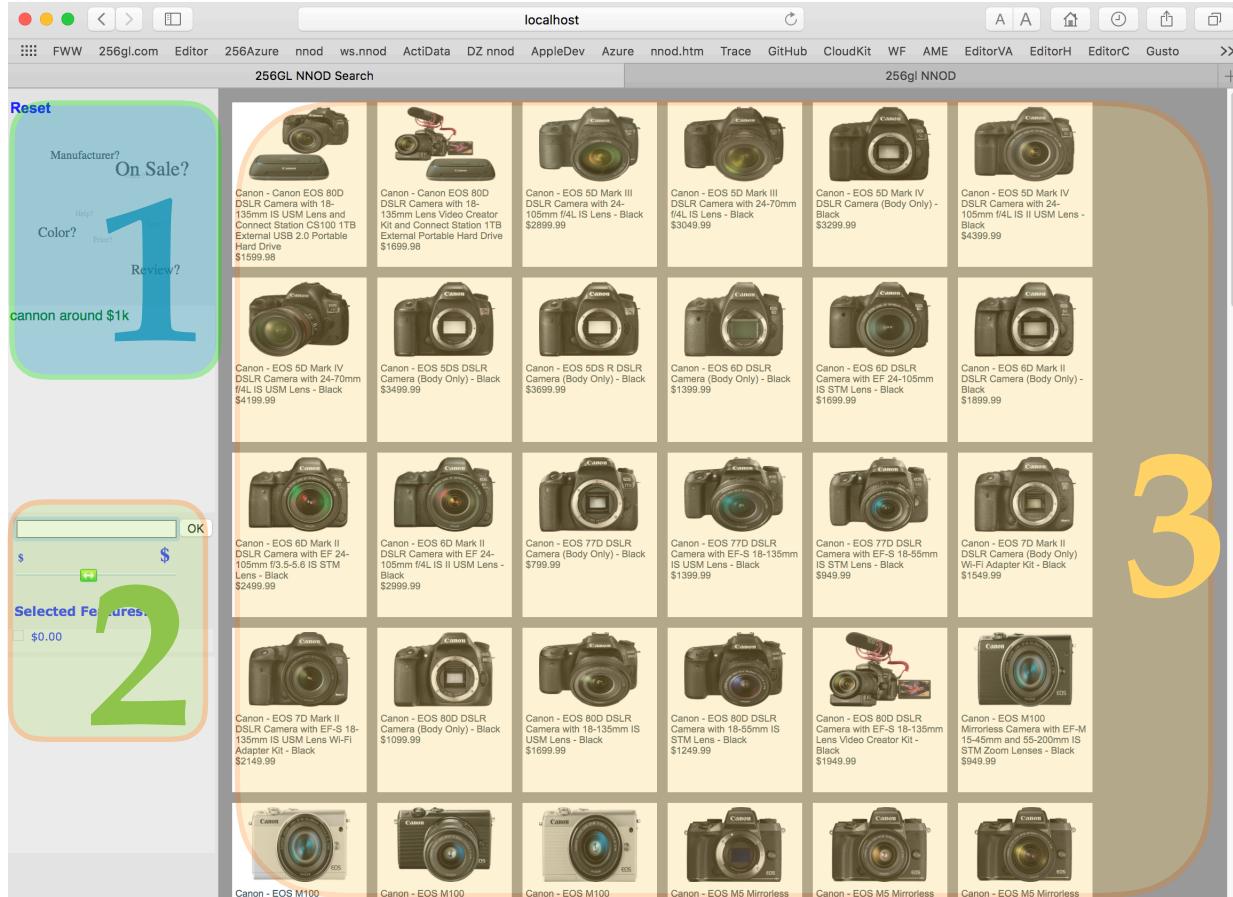

I am limiting this basic chatbot with only search of Product but the all possibilities (*opportunities*) to extend this solution with minimum modifications in the code could be done in the next versions.

Do not pretend!

One of the biggest problem of modern chatbots - they are *pretending*. Huge marketing and mass media “propaganda” of AI and Turing test, leads developers to the wrong design, when chatbots are built on the promise to *imitate a human*. When user meets such bot, the high expectation leads to many unreasonable attempts to ask questions, which bots unable to answer. And instead of using bot as a tool to improve search, in many cases users are trying to test it.

For this reason, my goal is to make clear understanding of the limit of an assistant (chatbot) that I developed. I am planning to show, that chatbot functionality is similar to “receptionist” and its capabilities are limited. But in many cases, what “a receptionist” would do - he/she would save a lot of visitor's time and lead you to the right person (expert) who would provide the best service helping to find the right products to satisfy your needs.

That's why the area 1 (cloud of tags) is the model of “chatbot's mind”.

When the visitor (user) understands that chatbot is helping to make the formal search request and bot “knows” only the limited number of parameters (which in many cases unknown in formal way to the visitor), the role of this chatbot will be clear and the process of search will be more satisfactory.

To show chatbot capacity and its limits I combined the content layer (3) together with the control layers (1 and 2).

The new page combined three components: 1 - show available parameters for search, 2 - dialog and state of current interaction, 3 - content.

As a future feature, I also added Selector (will require additional linguistic trigger per category) with BB products categories:

Day 4

Architecture, Integration and Multi Channel Chat

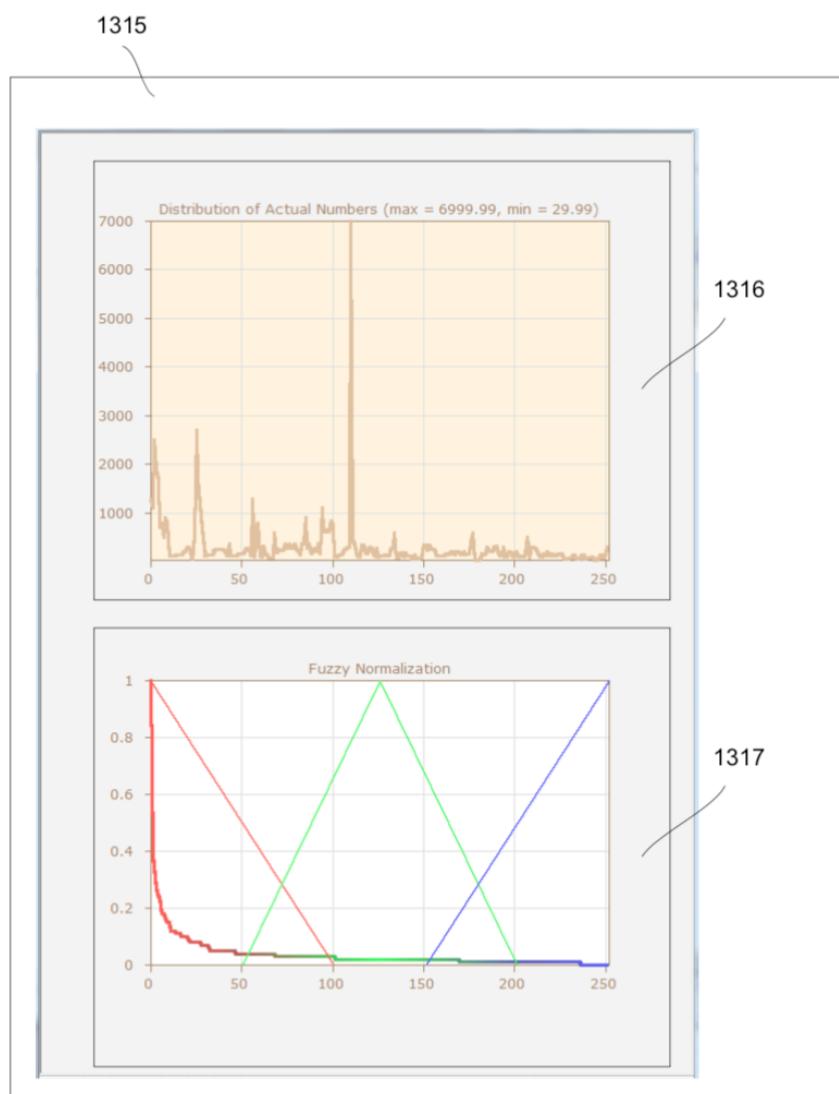

One of my goals in this project is to build not a single chatbot, but smart communication channel, capable to interact with various data sources (in our case BB API) by using different devices: PC with mouse and possible touch screen, smart phones, TV, smart home devices like Alexa. The various scenarios includes: the comprehensive interactive search from PC, the relaxed shopping in front of TV, the voice request for shopping notes using Alexa or Siri , and the help of the customer service person (human expert) at the store:

The Price is one of the most often used parameter in process of shopping. Making price parameter flexible in multi-channel search models is one of the most important objectives in my project. In “natural” conversation we often are using fuzzy requests: “around one hundred”, “my upper limit is \$1000”, etc. To solve this problem I am using the Fuzzy Set Theory introduced by [Lotfi Zadeh](#) in his Fuzzy Logic and specifically in the “[The concept of a linguistic variable](#)”.

Zadeh’s model allows us relatively easy calculate the numeric analog in linguistic terms. The model could be very simple initially, but because it based on solid formalization, it can grow as needed.

This model allows converting the natural language terms like “average”, “cheap”, “best”, etc. into the functions and then using these functions in the selection of requests. The result could be obtained based on basic mathematical equations.

Desktop version of our solution may use the slider to setup the price value based on intuitive perception of “more” or “less” (left or right) position of slider.

BB API has the response parameter called Facet:

The screenshot shows the 'Products API' interface on a web browser. On the left, there are three main sections: 'Search for Products', 'Build Your Response', and 'Pagination'. In the 'Build Your Response' section, under 'Product Attributes (optional)', the 'Regular Price' checkbox is selected. Below it, the 'Facets' section is highlighted with a green oval, showing 'Regular Price' selected with a number of 50. The 'Sort By' dropdown is set to 'Regular Price' with 'Ascending' selected. In the 'Facets' section, there is also a 'Number:' dropdown set to 50. At the bottom of this section, there are 'RESET Query' and 'RUN Query' buttons. To the right of the interface, a dark sidebar titled 'URL Breakdown' provides a detailed breakdown of the request URL. It includes the base URL, category ID, API key, sort options, show options, pagination, facets, and response format. Below this, the 'Complete URL' is shown as a copyable link. The 'response:' section shows the JSON output, which includes a 'facets' field containing a list of price ranges and their counts. An orange oval highlights this 'facets' field and its contents.

```
baseURL : https://api.bestbuy.com/v1/products
categoryId : (categoryPath.id=abcat0401000)
apiKey : ?apiKey=7ksBhjryZ5hxofJSEk2VB07u
sortOptions : &sort=regularPrice.asc
showOptions : &show=regularPrice
pagination : pageSize=100
facets : &facet=regularPrice,50
responseFormat : &format=json
```

```
#request: https://api.bestbuy.com/v1/products((categoryPath.id=abcat0401000)?apiKey=7ksBhjryZ5hxofJSEk2VB07u&sort=regularPrice.asc&show=regularPrice&facet=regularPrice,50&pageSize=100&format=json)
```

```
#response: { "regularPrice": 499.99 }, "facets": { "regularPrice": { "999.99": 12, "179.99": 11, "449.99": 11, "99.99": 10, "899.99": 10, "549.99": 8, "1199.99": 8, "69.99": 7, "199.99": 7, "599.99": 7, "649.99": 7, "119.99": 6, "159.99": 5, "279.99": 5, "399.99": 5, "499.99": 5, "699.99": 5, }
```

Facets may include the list of prices with their frequency. I have used this list for calculating the price range and distribution for particular selection of items from BB database.

The simple sorting and delta assigned to the current slider position allows (with minimum user's actions) select the product in price area called “around”

```
price = parseInt(price)
regularPrice_gt = price - price / 3;
regularPrice_lt = price + price / 3;
price = "regularPrice>=" + regularPrice_gt + "&regularPrice<="
+ regularPrice_lt;
```

At the same time I have prepared the list of all categories which currently labeled in BB databased with formal IDs and short linguistic definitions:

*abcat0502000 - Laptops
abcat0501000 - Computers
abcat0401000 - Cameras & Camcorders
pcmcat209400050001 - phones
abcat0204000 - Hesad phones

Day 5

Neural Network and Web sockets

The main goal for today is to connect the developed solution with NNOD based triggers and add communication channel (WebSocket) for integration with voice (Alexa as an example) and non-PC applications running in devices like smart TV (iTV as an example.)

I need a few more technical improvements in modules organizations and callbacks, and a final architectural review. In a “real world” development architectural review includes number of architectures:

My “virtual team” has discussed briefly all four architectures and the result is following:

1. The arguments in internal calls must be kept as a “state” to support dynamic state based linguistic model.
2. The connection channel must be added separately from the presentation (gallery) layer.
3. The connection channel must support asynchronous protocol.

4. To support Alexa, which skills have 8 second silence timeout, the session must be identified properly and when connection potentially restored, the particular session must remember the previous conversation.
5. Mobile devices have fundamentally different screen and interaction UI, that only presentation layer could be re-factoring in different environments.
6. One of the frequent scenario (using finger to point) is - "I like something like this, but cheaper" or "better", and this scenario could be implemented when user click or select the item, and parametric definition of this item becomes the current active state.
7. Cleaning parameters from the current selection is important when the search reach the "dead end" (the request with particular set of parameters doesn't return any items from the database).
8. The technical specification (Zoom, Memory, Matrix, etc.) is important and the potential extension of linguistic triggers should not affect the code itself.
9. Software must be irrelevant to the linguistic content: if I want to make chatbot helping with the search for different product (for example – a bottle of wine), a very minimum adjustments should be required in basic software.

Dialog:

Buyer: I'm looking for camera.

SP: Here are a few to choose from. Which do you like the best?

Buyer: I think this one. Do you have similar, but cheaper?

SP: Yes, but these have slightly less features.

Buyer: I like Sony.

SP: Very well. Then look at this one.

Buyer: Any model with better resolution?

SP: This one - Sony MVC. Has Disk Recording feature.

Buyer: Nice. Just a little too heavy.

etc..

Data Base:

Model	Make	Price	ZOOM	SCU
LS443	Kodak	\$429.99	3	41778439289
EasyShare DX4330	Kodak	\$296.99	3	41771580506
DiMAGE S304	Minolta	\$573.49	4	43325992247
DiMAGE 7Hi	Minolta	\$1,196.99	7	43325993374
DiMAGE X	Minolta	\$389.49	3	43325992780
Coolpix 4500	Nikon	\$631.99	4	18208255030
Coolpix 5700	Nikon	\$1,047.99	8	18208255047
Coolpix 885	Nikon	\$469.49	3	18208255054
MVC-CD400	Sony	\$890.99	3	27242606487
MVC-CD250	Sony	\$595.99	3	27242606524
MVCCD300	Sony	\$858.99	3	27242589223
MVC-CD200	Sony	\$578.99	3	27242589247
Cyber Shot DSC-S75	Sony	\$494.99	3	27242589278
Cyber Shot DSC-P2	Sony	\$390.99	3	27242607354

SQL Interface:

```

SELECT * FROM Cameras WHERE Price < $800 AND Price > $300
SELECT * FROM Cameras WHERE Price < $800 AND Price > $300
AND MAKE = 'Sony'
SELECT * FROM Cameras WHERE Price < $500 AND Price > $200
AND MAKE = 'Sony' AND ZOOM > ...

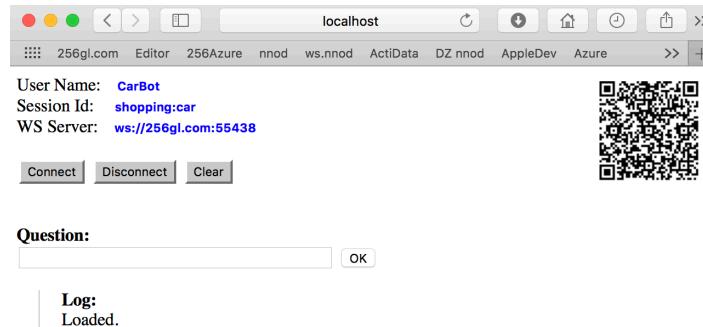

```

There are two additional areas of using this bot in the real life:

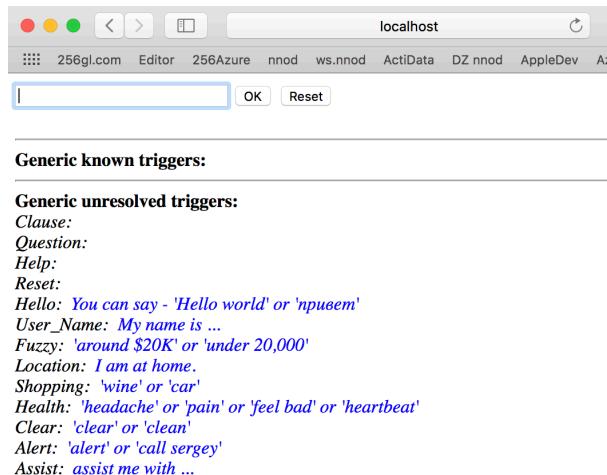

1. The similar to [Audio Tour in MIA](#), but shopping tour in [MOA](#)
2. The home shopper - interactive second screen to ShopNBC, HSN TV, etc. channels.

In the preparation for the final integration I have added two [NNOD API](#) JavaScript templates: [nnod_bot.htm](#) and [nnod_page.htm](#) to my solution.

[nnod_bot.htm](#) - the template for WebSocket communication channel which allows connecting Alexa or Siri to presentation layer:

[nnod_page.htm](#) - the template allow experimenting with near triggers:

Day 6

Integration.

In the real Programming to write a code is not a goal. The goal and the nature of a “good” programmer are to write an efficient, reusable, and possibly beautiful code which may live long. There are a few software projects in which my code survived 10 years and longer, and my goal in this project is to create the solution which may live long and evolve. The neural triggers were created more than 20 years ago and I am now going to use almost exact JavaScript version of Java based classes of neurons created back then. The environment had changed dramatically, but the neurons are almost the same.

Every programmer is unique in a way how he/she code. In this project actual coding (typing lines of code) takes about 30% of the all-time of thinking, preparing and organizing tools. Today's morning result of the overnight architectural review is following:

1. The desktop version should be implemented without voice interface, for the reason that the mouse or finger is more efficient than voice control.
2. TV, Smart Home interactive channels, Interactive Screens must be voice capable.
3. SmartPhones and tablets must have integration of voice and touch.

The collage includes the following components:

- Smartphone Screenshot:** Shows a "Chat" screen with a grid of wine bottle icons and a message from "Sergei_rpo9v". The status bar shows 9:41 AM, 100% battery, and signal strength. Buttons at the bottom include a microphone icon, a camera icon, and a share icon.
- Architectural Diagram:** A network diagram showing "Smart Homes" connected to a "User", a "Smart TV", and a "Smart Second Screen". These devices are connected via the "Internet" to a "TV Networks" cloud (containing "Direct TV") and "Personal Clouds" (containing "Skilled Virtual Agents").
- Family on Bed:** A photo of a family (adult and three children) sitting on a bed, looking at a large Smart TV displaying a media interface with various app icons.
- Smart TV Interface:** A list of voice commands:
 - Switch to TPT2
 - Record this episode
 - I like this movie
 - Help me to find a movie for tonight
 - I want to buy this
 - ...
- Smart TV Product Details:** A screenshot of a product listing for a digital camera:

Make	Nikon
Type	Mirror-less
Zoom	10X
Price	Under \$1000
Color	20 MP
- Smart TV Product Details:** A screenshot of a product listing for a car:

Make	BMW
Model	3 series
Transmission	Automatic
Engine	
Body	
Year	
Price Range	Under 30K
Color	
- Alexa Device:** A physical Amazon Echo smart speaker.

The result of integration NNOD template, the neural triggers with BB Web page is a set of 6 JavaScript/XML files:

1. index.html - the upper entry point
2. bb_page.html - control center with inputs, outputs and bridge between all components
3. bb_page.js - JavaScript module which controls neural triggers state, additional loading, and services functions like reset

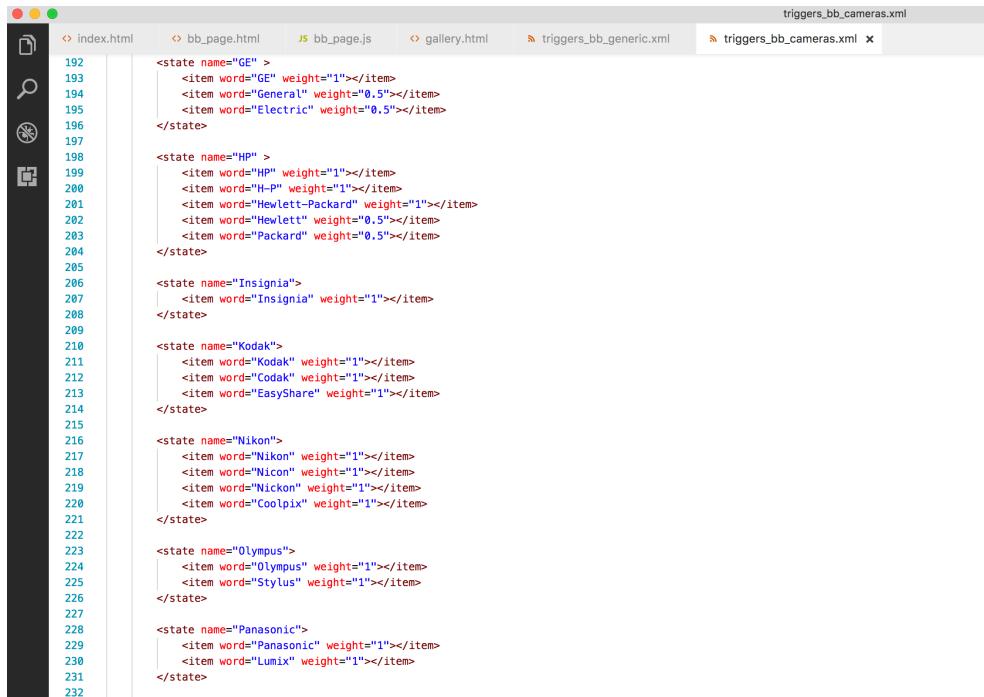

```
bb_page.js
index.html  bb_page.html  JS bb_page.js  gallery.html  triggers_bb_generic.xml  triggers_bb_cameras.xml

1 var generic_triggers_url = "triggers/triggers_bb_generic.xml";
2 var cameras_triggers_url = "triggers/triggers_bb_cameras.xml";
3
4 var linguistic_URLs = [];
5 var layers = [];
6 var layer = null;
7 var url;
8
9 var words_layer = null;
10 var generic_triggers_layer = null;
11
12 function load_nnod() {
13     words_layer = Add_Neuro_Layer(1, -1, 1, 50000, "words");
14     generic_triggers_layer = Build_Neural_Layer(generic_triggers_url);
15     generic_triggers_layer.Disharged_CallBack = Show_Neural_State;
16     layers.push(generic_triggers_layer);
17     Save_Linguistics_URL(generic_triggers_url);
18
19     linguistic_URLs = Restore_Linguistics_URLs();
20
21     if (linguistic_URLs != null) {
22         for (var i = 0; i < linguistic_URLs.length; i++) {
23             url = linguistic_URLs[i];
24             if (url == generic_triggers_url) continue;
25             layer = Build_Neural_Layer(url);
26             layers.push(layer);
27             Save_Linguistics_URL(url);
28         }
29     }
30
31     Restore_Neural_State(generic_triggers_layer);
32     for (var i = 0; i < layers.length; i++) {
33         Restore_Neural_State(layers[i]);
34     }
35     Show_Neural_State();
36     linguistic_URLs = Restore_Linguistics_URLs();
37 }
38
```

4. gallery.htm - presentation layer and interface to BB API

5. triggers_bb_cameras.xml - neural linguistic triggers which supports Cameras category

6. triggers_bb_generic.xml - neural linguistics triggers responsible for general conversation, recognition of new categories, FAQ, etc.

```

```

Layer with key context triggers

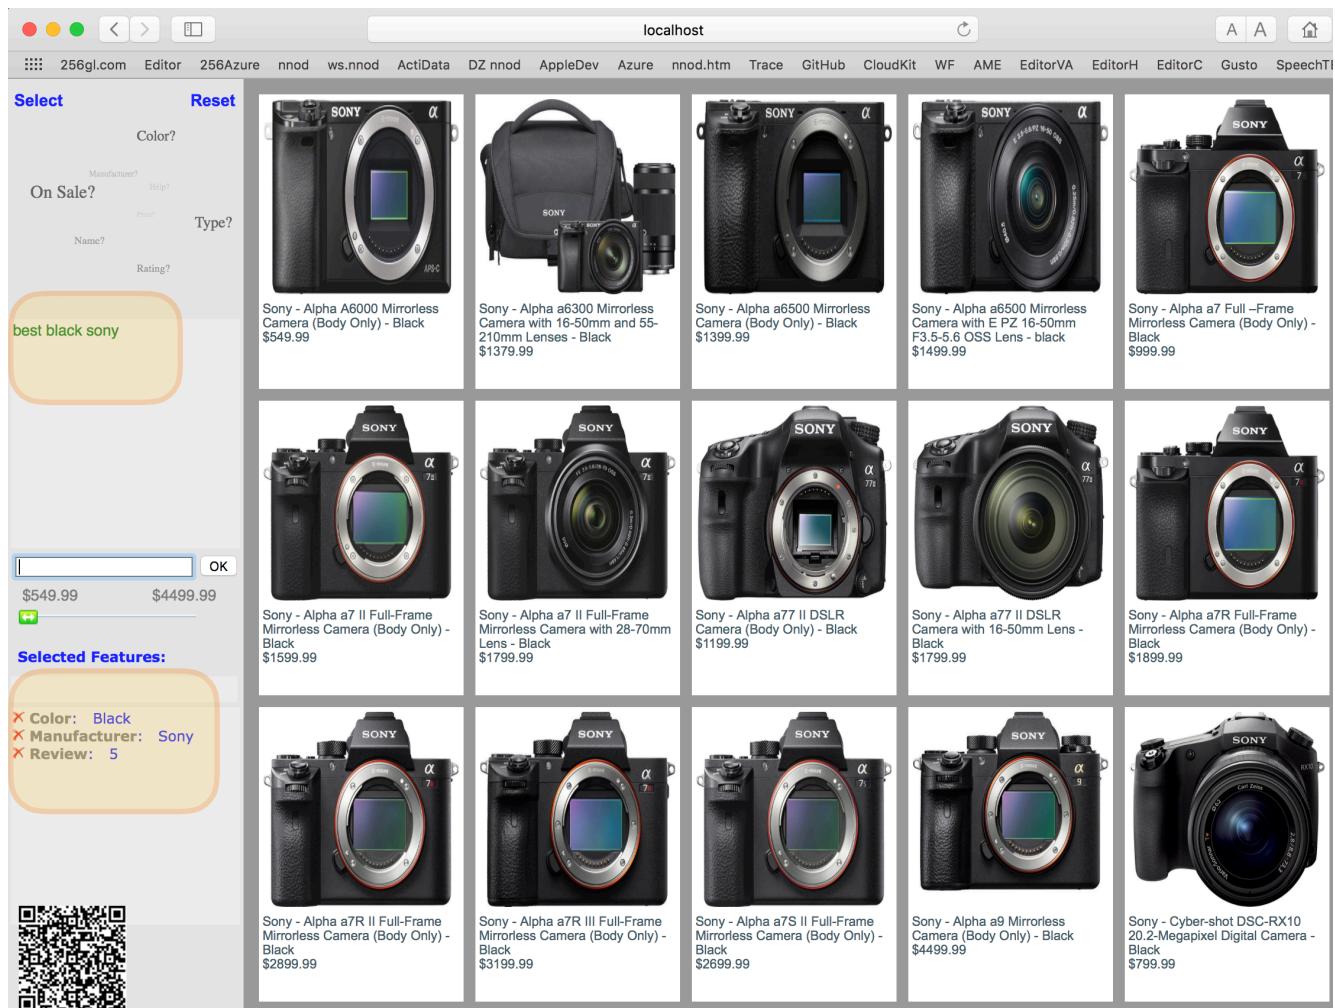

Layer with fuzzy normalized meanings

The result:

Day 6 outcome.

- All basic components for desktop version of chatbot connected and first version is working now.
- Online version available on [256gl.com](http://256gl.com/neurons/bestbuy/index.html) (<http://256gl.com/neurons/bestbuy/index.html>)

Day 7

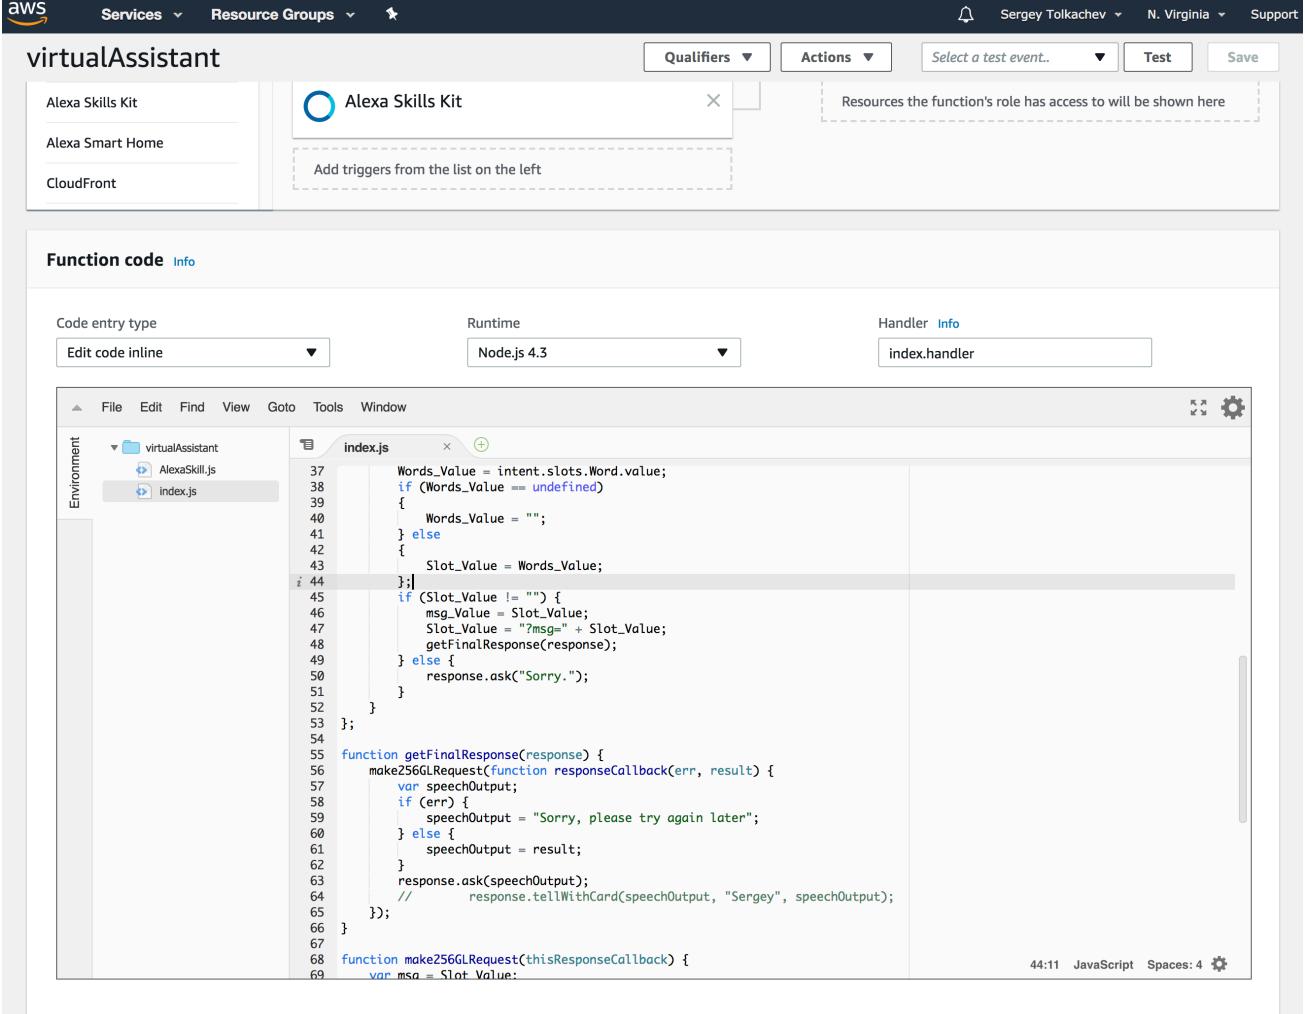

WebSockets, Alexa, iOS InterActor, iTV

The goal for the last day of my project is to connect voice capable devices to the gallery.

1. Alexa

Alexa solution based on simple Alexa skill published in Amazon AWS, .aspx page on IIS and Node.js WebSocket bridge.

Alexa skill is a simple Voice to Text script connected to the external process through another simple.aspx

The screenshot shows the AWS Lambda function editor for a skill named "virtualAssistant". The top navigation bar includes "Services", "Resource Groups", "Qualifiers", "Actions", "Select a test event...", "Test", and "Save". The main area displays the "Alexa Skills Kit" configuration, with a note to "Add triggers from the list on the left". Below this, the "Function code" tab is selected, showing the "Info" section with "Code entry type: Edit code inline", "Runtime: Node.js 4.3", and "Handler: index.handler". The code editor window contains the "index.js" file with the following content:

```
37 Words_Value = intent.slots.Word.value;
38 if (Words_Value == undefined)
39 {
40     Words_Value = "";
41 } else
42 {
43     Slot_Value = Words_Value;
44 }
45 if (Slot_Value != "") {
46     msg_Value = Slot_Value;
47     Slot_Value = "?msg=" + Slot_Value;
48     getFinalResponse(response);
49 } else {
50     response.ask("Sorry.");
51 }
52 };
53 };
54
55 function getFinalResponse(response) {
56     make256GRequest(function responseCallback(err, result) {
57         var speechOutput;
58         if (err) {
59             speechOutput = "Sorry, please try again later";
60         } else {
61             speechOutput = result;
62         }
63         response.ask(speechOutput);
64         // response.tellWithCard(speechOutput, "Sergey", speechOutput);
65     });
66 }
67
68 function make256GRequest(thisResponseCallback) {
69     var msa = Slot_Value;
```

```

...
function getFinalResponse(response) {
    make256GLRequest(function responseCallback(err, result) {
        var speechOutput;
        if (err) {
            speechOutput = "Sorry, please try again later";
        } else {
            speechOutput = result;
        }
        response.ask(speechOutput);
        //           response.tellWithCard(speechOutput, "Sergey",
        speechOutput);
    });
}

function make256GLRequest(thisResponseCallback) {
    var msg = Slot_Value;
    var endpoint = 'http://.../alexa/alexa_virtual.aspx' + msg;

    http.get(endpoint, function (res) {
        var responseString = "";
        res.on('data', function (data) {
            responseString += data;
        });
        res.on('end', function () {
            thisResponseCallback(null, responseString);
        });
    });
}
...

```

When the connection between Alexa Voice Box and Skill in AWS established, the result of voice recognition will be forwarded to alexa_virtual.aspx:

```

<script language="C#" runat="server">
    public string session_id = "my_virtual";
    public string websocket_Server = "ws://....";
    public string msg = "";
    public string respond = "";
    public string prefix = "QA:";
    public WebSocket ws;
    public Semaphore sema;

    public void Page_Load(object sender, EventArgs e)
    {
        msg = Request["msg"];
        if (msg == null) msg = "Hello";
        var ws = new WebSocket(websocket_Server);
        ws.OnMessage += (ws_sender, ws_e) => OnMessage(ws_e);
    }

    protected void OnMessage(WebSocket ws)
    {
        ws.Close();
    }

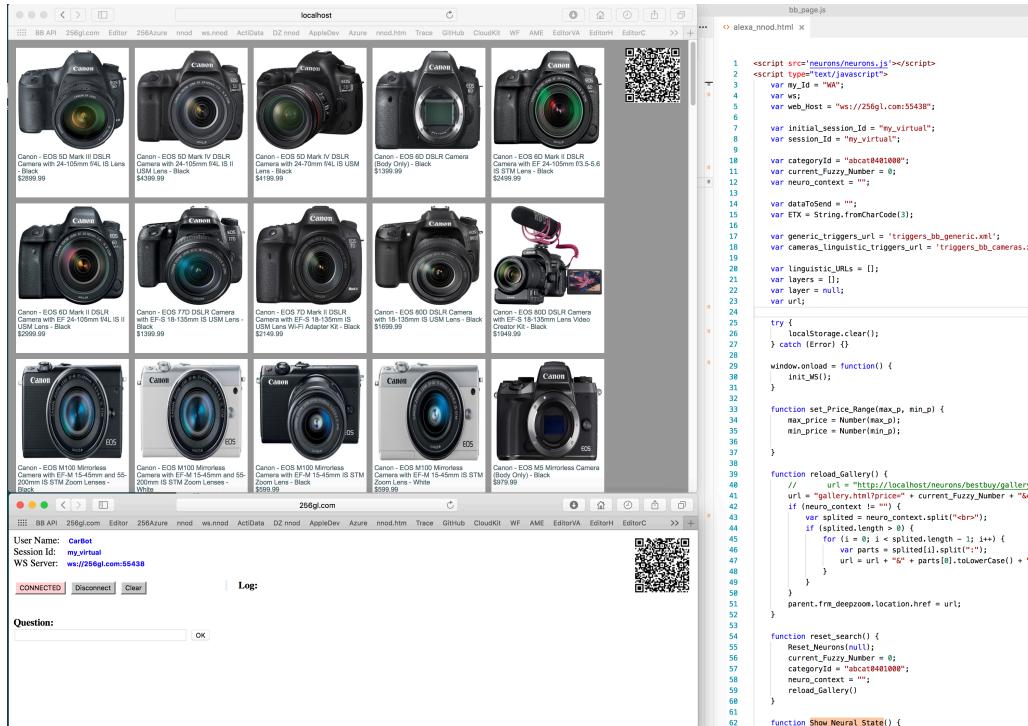

```

```
        ws.Connect();
        ws.Send("Session_Id=" + session_id);
        ws.Send(prefix + msg);
        sema = new Semaphore(0, 1);
        sema.WaitOne();
        if (ws != null) ws.Close();
    }
protected void OnMessage (MessageEventArgs e)
{
    var data = e.Data.Split(':');
    if (data.Length > 1)
    {
        respond = e.Data.Replace(data[0] + ":", "");
    }
    else
    {
        respond = e.Data;
    }
    sema.Release(1);
}
</script>
<%=respond%>
```

Because Alexa has 8 seconds (crazy) timeout and doesn't support a full scaled duplex connection yet, my solution based on async processing in C#. The program includes Semaphore to put the process in wait state, until the external process will signal it's complete or Alexa will disconnect because of the timeout. This will allows to cleanup parallel processes in highly unreliable interaction.

These pair of programs support: one part of the solution which could be connected to any content provider, and another part - “presentation layer” with WebSocket, which will react to voice commands from Alex, keep context and change its content.

To do this, I am merging [nnod_bot.htm](#) template with [gallery.html](#) -> [gallery_ws.htm](#)

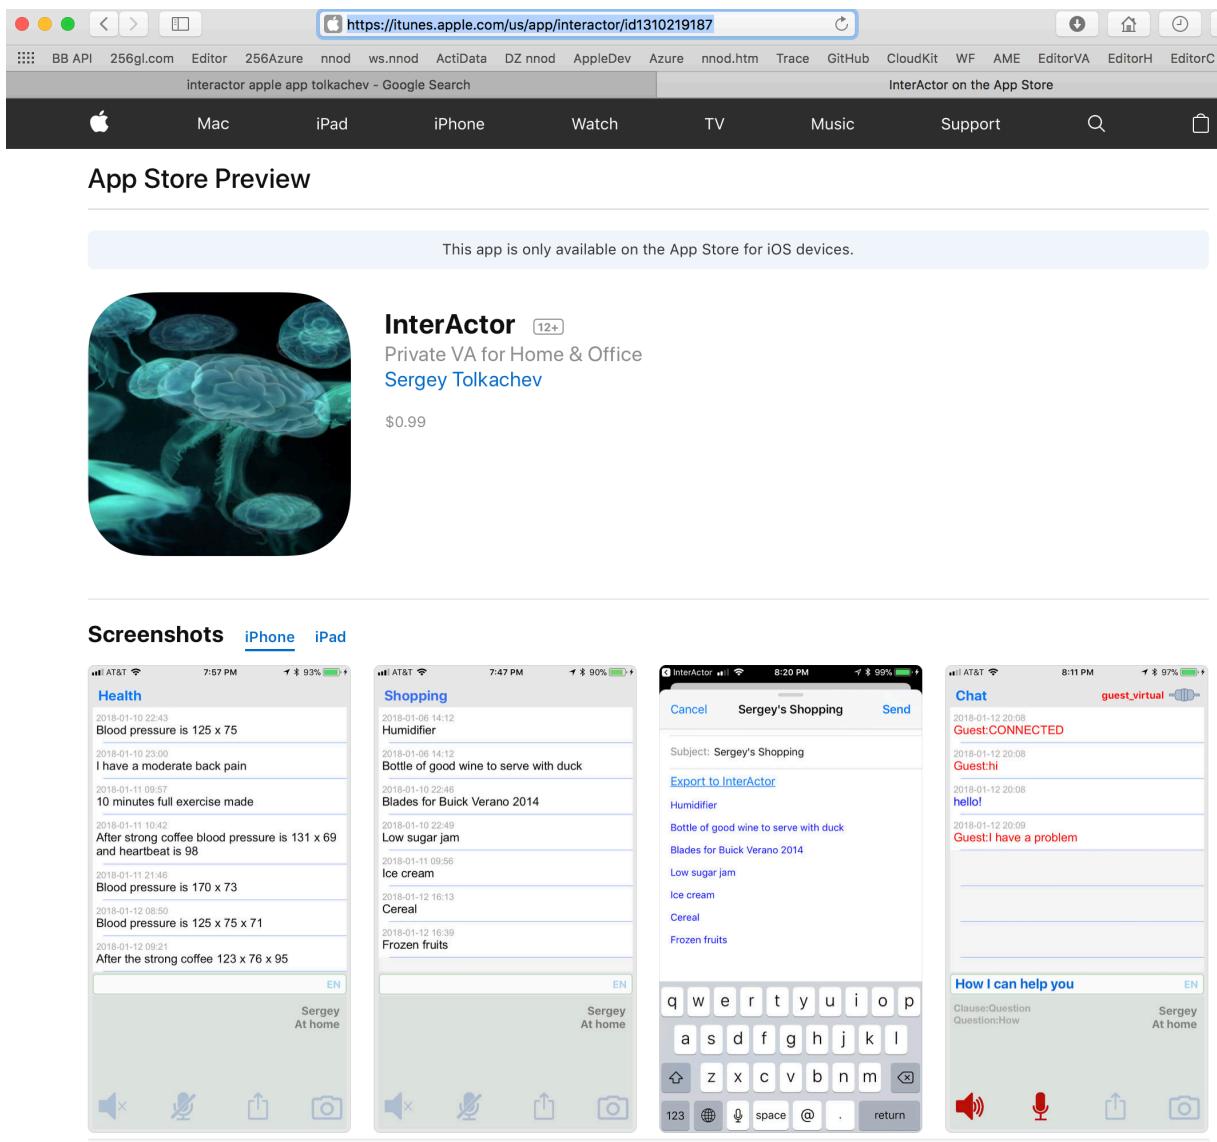

2. Node.js

[WebSocket server](#) - simple full duplex bridge between components could be implemented under node.js server in the cloud or local network. I have scalable node.js application in MS Azure and development version of the same application running on MS Virtual Machine on one of my servers.

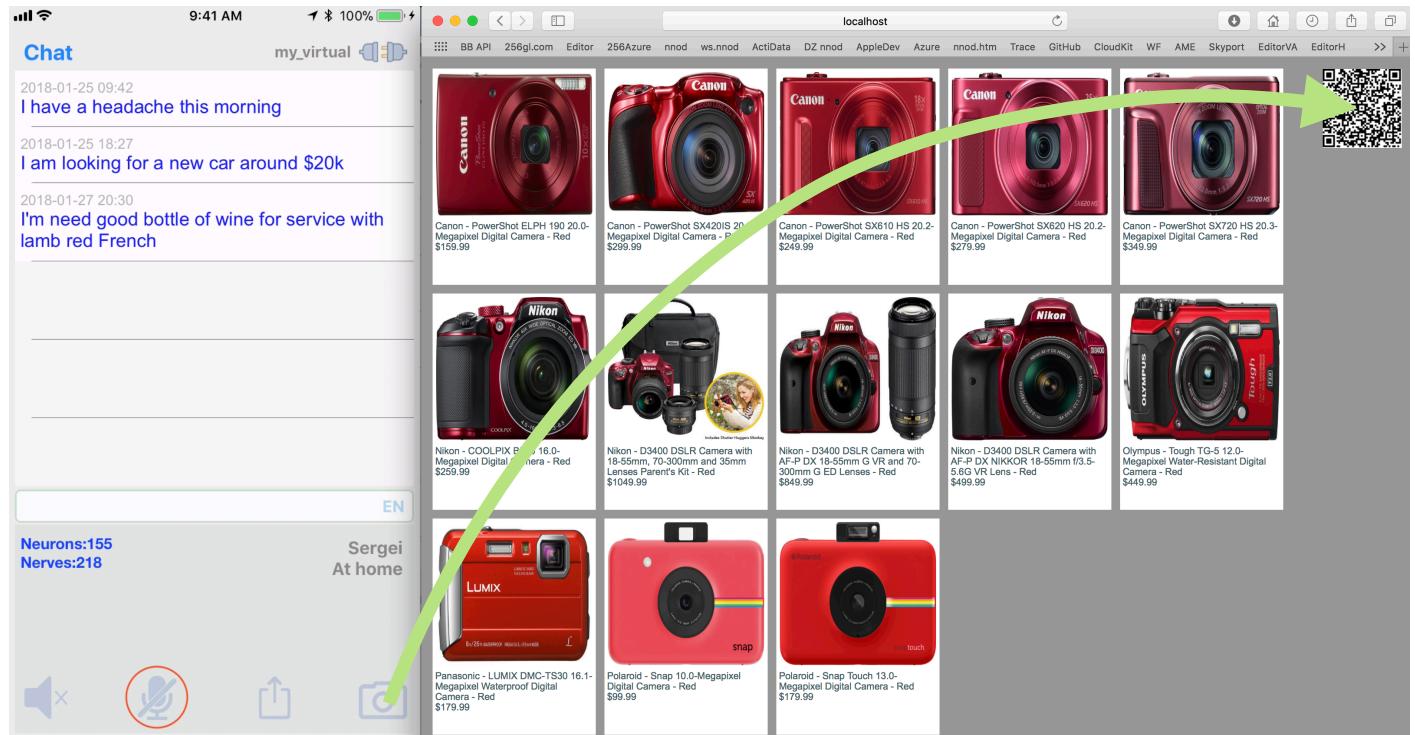

3. InterActor

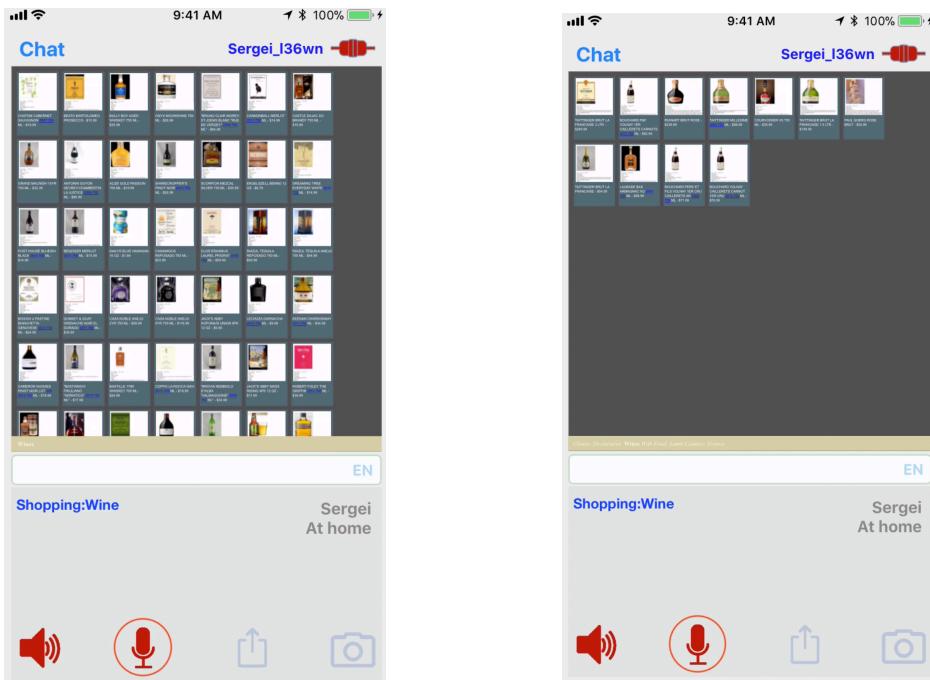

I developed [InterActor](#) as alternative to Alexa. Siri allow using voice recognition inside iPhone without connection to external servers. This application can be used as a personal recorder or voice assistant, similar to Alexa but more flexible and convenient.

InterActor allows connecting to the same page as Alexa, and using Siri voice recognition to control content, but at the same time, InterActor allows loading this page inside its WebView and using chat, voice or touch to search for product or service. For example, I can load wine selector and use requests like: "French red for a lamb" or "Italian good with pasta", etc. And the wine selector is identical to the BB Cameras selector; instead the API to the Database is different.

InterActor have QR barcode recognizer and WebSocket which allows to pair two pieces together and establish stocked to socket connection.

256gl.com/neurons/wine/
