

ChatBot in 7 Days

How to use Neural Networks to create Chatbot in a week

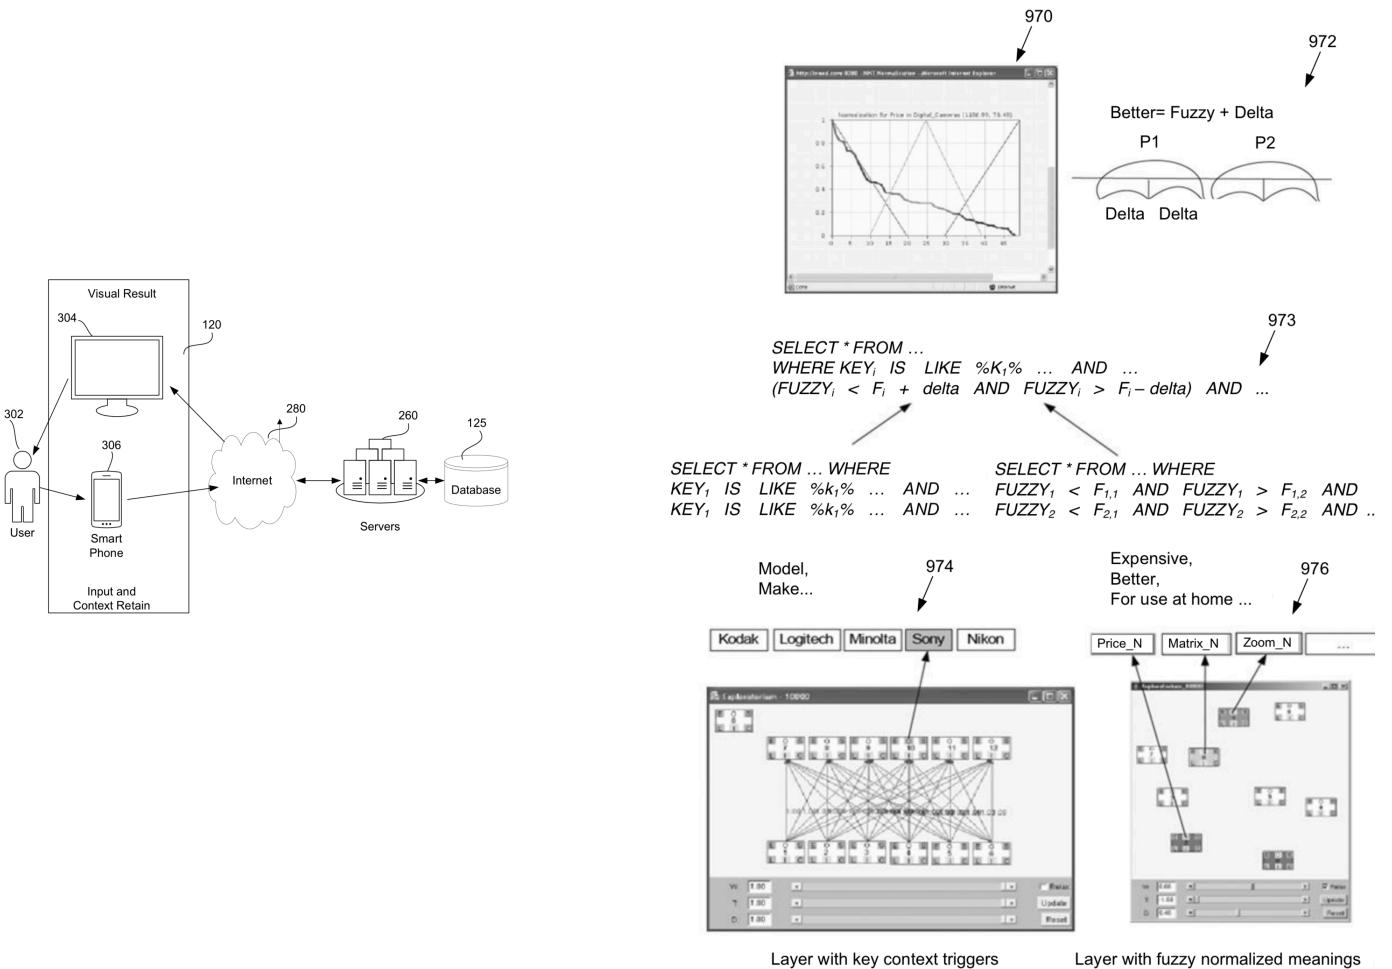

Development Diary: February 22, 2018 - February 28, 2018

Best Buy

Introduction

In this project we will create a ChatBot or Virtual Assistant, capable to run in multi channel environment (chat, voice, PC, smartphone, TV) by using neural networks NNOD SDK and very basic development resources. The goal is to show how easy is the process of building interactive contextual search Assistant when using Neural Networks based Expert System. As an example we will use BestBuy website and its Development API. The process will takes one man-week, and I will keep the diary with daily report.

Day 1

Project preparation. Agile vs Waterfall. Data Source.

Before to start any projects, somehow, the decision about planning and final goal must be made. But I will be the only one working on it during the next 7 days, so all traditional function: management, architectural design, UI, front and back programming, QA and few others, will be implemented inside the one man's mind. Personally, I prefer the Waterfall model, but considering that I will have minimum possible resources allocated to this project, I've decided to use Agile as my personal method to communicate. Which means that "virtual manager", "virtual architect", etc. will "virtually" interact in my mind representing the model of real team cooperation.

Learning Best Buy API.

The very first step - registration on BestBuy Development site and obtaining API key. To do this we registered on <https://developer.bestbuy.com> and feel application form to obtain API Key. This Key required to send requests to BestBuys database.

The next step is to learn and experiment with BestBuy API (BB API). It takes some time to understand the structure, component, formats of API. The most important for us is Query Builder - <http://bestbuyapis.github.io/bby-query-builder/#/productSearch> Most of the time we spent to understand the structure of JSDON queries and responds.

For example, informal request - "Show me cameras around \$200 with the best reviews" can be reformulated in formal request:

At the same time, on the background, we start architectural design and preparation for presentation of responses in more dynamic visual form.

To make this solution generic as possible, we will use basic Web Server and will build interactive chat page using only standard JavaScript.

Our Neural Network API published as Open Source under GNU license in GitHub, and we will add this solution into the same GitHub depository.

Local Development Environment.

Products API

The Products API gives you access to the full Best Buy catalog. The query builder provides a subset of the product attributes to create sample requests and response documents.

1 Search for Products

You can search by one of our more popular categories, an attribute value, keyword or any combination of these:

Digital Cameras

Enter Keyword(s)

Regular Price > 100

Regular Price < 300

Customer Review Average >= 4

2 Build Your Response

Product Attributes (optional) Select All Select None

Name Regular Price Image URL

Customer Review Average

Facets:

Regular Price Number: 50

Sort By:

Customer Review Average Sort Order: Descending

3 Pagination

Specify additional results per page or return subsequent pages by updating the Results Per Page and Page values:

Results Per Page: 100 Page: 1

RESET Query RUN Query

URL Breakdown

Here is an anatomy of your request, showing all of the "pieces" that make up your complete URL:

```

baseURL : https://api.bestbuy.com/v1/products
categoryId : (categoryPath.id=abcatalog0401000)
attribute :
(regularPrice>100&regularPrice<300&customerReviewAverage>=4)
apiKey : ?apiKey=7ksBhjryZ5hxofjSEk2VB07u
sortOptions : &sort=customerReviewAverage.dsc
showOptions :
&show=name,regularPrice,image,url,customerReviewAverage
pagination : pageSize=100
facets : &facet=regularPrice,50
responseFormat : &format=json

```

Complete URL

```
#request: https://api.bestbuy.com/v1/products(regularPrice>100&regularPrice<300&customerReviewAverage>=4&(categoryPath.id=abcatalog0401000))?apiKey=7ksBhjryZ5hxofjSEk2VB07u&sort=customerReviewAverage.dsc&show=name,regularPrice,image,url,customerReviewAverage&facet=regularPrice,50&pageSize=100&format=json
```

#response:

```
{
  "from": 1,
  "to": 40,
  "currentPage": 1,
  "total": 40,
  "totalPages": 1,
  "queryTime": "0.123",
  "totalTime": "0.243",
  "partial": false,
  "canonicalUrl": "/v1/products(regularPrice>100&regularPrice<300&customerReviewAverage>=4)&(categoryPath.id=abcatalog0401000))?show=name,regularPrice,image,url,customerReviewAverage&sort=customerReviewAverage.dsc&pageSize=100&format=json&facet=regularPrice,50&apiKey=7ksBhjryZ5hxofjSEk2VB07u",
  "products": [
    {
      "name": "Panasonic - LUMIX DMC-TS30 16.1-Megapixel Waterproof Digital Camera - Blue",
      "regularPrice": 179.99,
      "image": "https://img.bbstatic.com/BestBuy_US/images/products/4032/4032159_ra.jpg"
    }
  ]
}
```

The whole process will be made in Mac OS but there are no any differences in the implementation for Windows. We will use Apache Web Server on Mac and IIS Web Server on Windows.

To make the very first call to BB API we can use PHP:

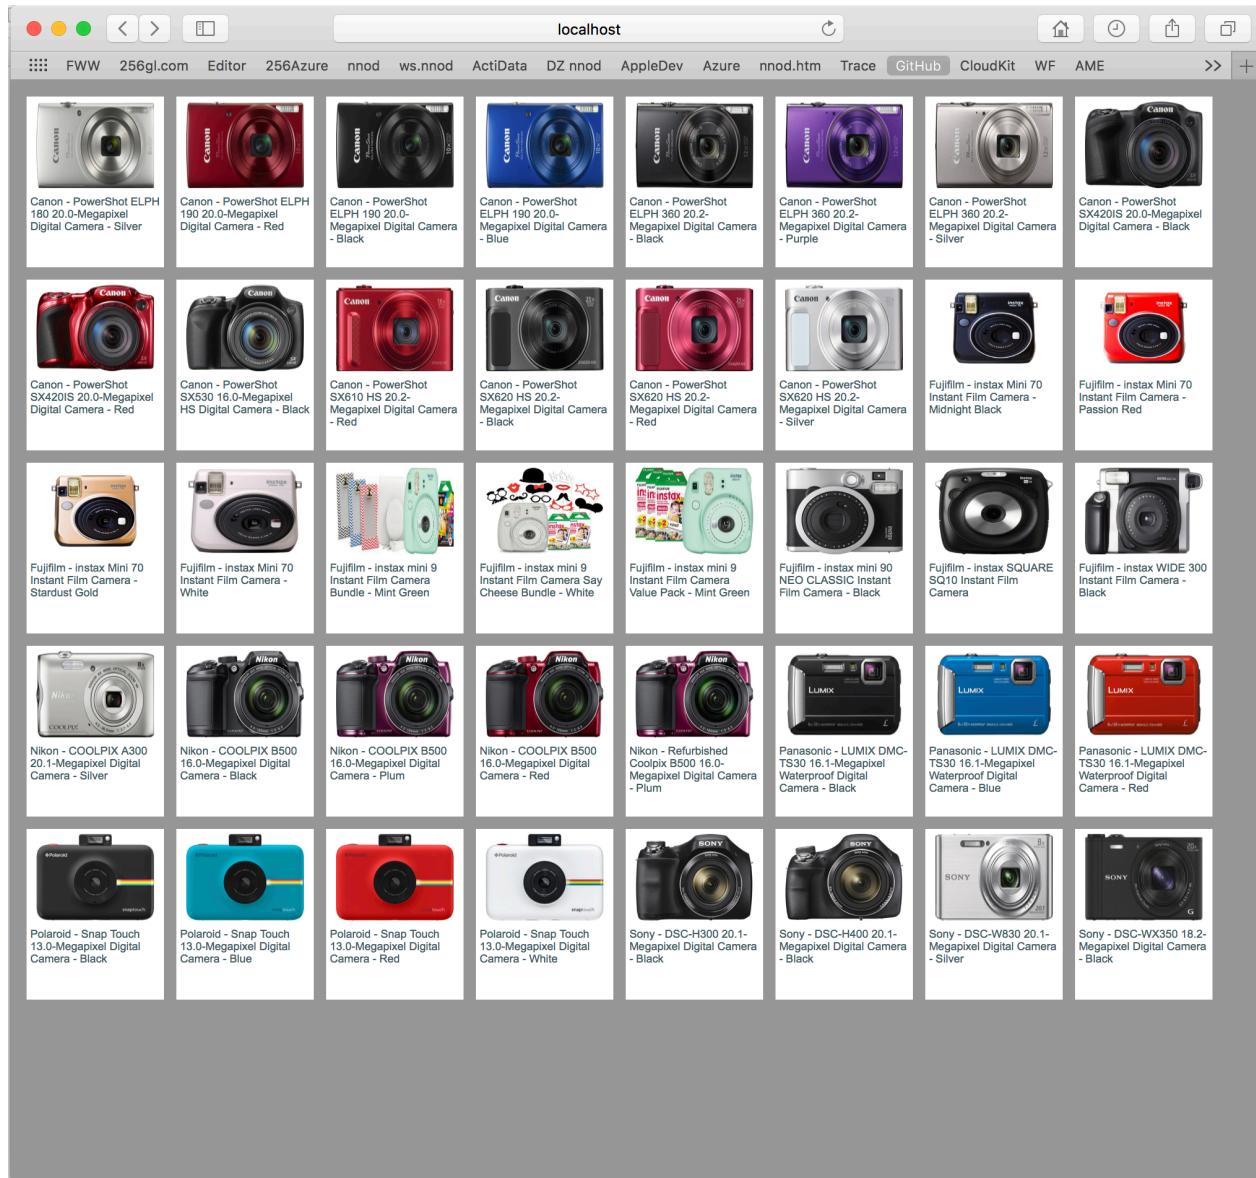

```
<body style="background-color:#999999;">
<?php
$url = "https://api.bestbuy.com/v1/
products(customerReviewAverage%3E=4&regularPrice%3E150&regularPrice%3C250&(ca
tegoryPath.id=abcatalog0401000))?
apiKey=xxxxxxxx&sort=name.asc&show=manufacturer,name,image,url,regularPrice&fa
cet=regularPrice,50&pageSize=100&format=json";
$data = file_get_contents($url);
$json = json_decode($data, true);
$array = $json[ "products" ];
$db_counter = 1;
foreach ($array as $obj) {
```

```

$db_counter = $db_counter + 1;
echo "<div class=\"thumbnail_wrapper\"><table cellspacing=\"0\" cellpadding=\"0\"><tr>\n".
"    "<td id=\"td_thumbnail_\" . $db_counter . \"\"
class=\"td_thumbnail_image\">\n".
"        "<a href=\"#\"><img src=\"\" . $obj[ 'image' ] . \" height='70' width='95'
\" .
"            \" onclick=\"javascript:openThumbnailLink('" . $obj[ 'url' ] . "'); return
false;\"></a></td>\n".
"    "</tr><tr><td id=\"td_thumtitle_\" . db_counter . \"\"
class=\"td_thumbnail_title\">\n".
"        \" . \" . $obj[ 'name' ] . \"\n".
"    "</td></tr></table></div> \n\n";
}
?>
</body>

```

The result:

Day 1 conclusion.

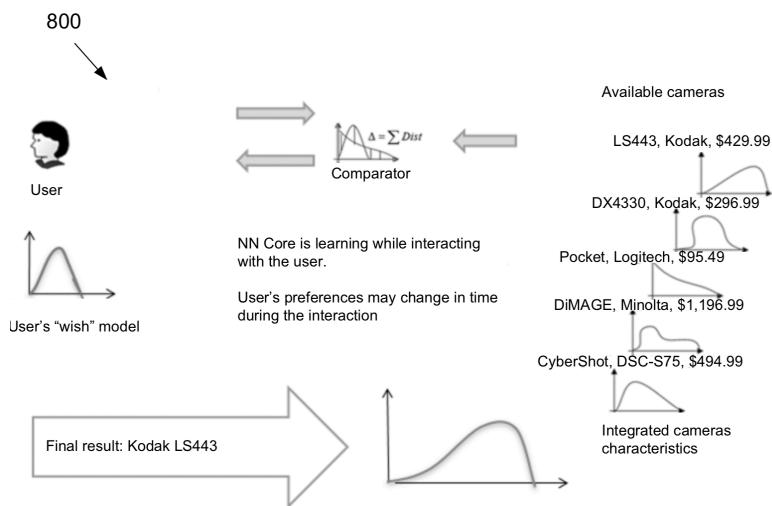

BB API Key obtained and we have full access to BB DataBase. The very first Web Page with implementation of requests to BB API built. Clear understanding of BB API now allow to start building Linguistic model for interactive search.

Day 2

Architectural/Marketing.

Value - one of the most critical questions needed to be answered before and during any development. What is the criteria we should put to measure the project advantages from similar? In our case we will use Cost of service and User's Information Demand satisfaction.

When User get an idea about buying something, he/she need to gather some information about the product. And before the very last moment when sale completed, the information for decision making will be gathered from many sources. Web, personal notes, social networks and finally expert are the network of participants in interactive process of finding the best possible item from many available in variety of sources.

Basically the process includes collecting data from different sources, compare result and repeat the process until the threshold level for the decision reached.

The cost of this process has two components: User's cost, which includes the time and potential difference if the item is wrong, or the same item can be purchased cheaper. And sale's coat, which includes the cost of consulting, and potential cost of loosing the client if he/she decided to switch to different store because of whatever reason.

We will use Best Buy Web site as one of the sources for measuring success. Criteria #1 will be based on the time required for the user to find enough information about the product and make decision to move forward and visit Best Buy or to switch to another retailer.

PHP -> JavaScript.

Even PHP is very popular and widely supported language, wherever it is possible we will try to use JavaScript for the reason of minimization of support and scalability. If our solution will be fully JavaScript based and will not require any external server support, but only BB API, that's mean we automatically solve the problem of scalability.

Changing PHP to JavaScript is relatively easy:

```
<!DOCTYPE HTML>
<html>
<head>
    <meta http-equiv="X-UA-Compatible" content="IE=edge" />
    <meta http-equiv="content-type" content="text/html; charset=UTF-8" />
    <meta name="apple-mobile-web-app-capable" content="yes" />
    <meta name="apple-mobile-web-app-status-bar-style" content="black" />
    <meta name="viewport" content="minimum-scale=1.0, maximum-scale=5.0, user-scalable=yes, initial-scale=1.0" />
    <meta name="viewport" content="user-scalable=yes">

    <title>256gl NNOD</title>
    <link rel="stylesheet" type="text/css" href="style.css" />
    <script type="text/javascript">
        function openThumbnailLink(url) {
            window.open(url, "_blank", "toolbar=no, scrollbars=yes, resizable=yes,
top=10, left=10, width=800, height=800");
            return true;
        };
    </script>
</head>
<body style="background-color:#999999;">
    <div id="demo"></div>
    <script>
        var xmlhttp = new XMLHttpRequest();
        xmlhttp.onreadystatechange = function() {
            if (this.readyState == 4 && this.status == 200) {
                var myObj = JSON.parse(this.responseText);
                var result = myObj.products;
                var x = "";
                for (i in result) {
                    x = x + "<div class=\"thumbnail_wrapper\"><table
cellspacing=\"0\" cellpadding=\"0\"><tr>\n" +
                        "<td id=\"td_thumbnail_" + i + "\""
class="td_thumbnail_image\">\n" +
                        "<a href=\"#\"><img src=\"" + result[i].image + "\"
height='70' width='95' " +
                        "\" onclick=\"javascript:openThumbnailLink('" +
result[i].url + "'); return false;\"></a></td>\n" +
                        "</tr><tr><td id=\"td_thumbtile_" + i + "\""
class="td_thumbnail_title\">\n" + " " + result[i].name + "<br>$" +
result[i].regularPrice + "\n" +
```

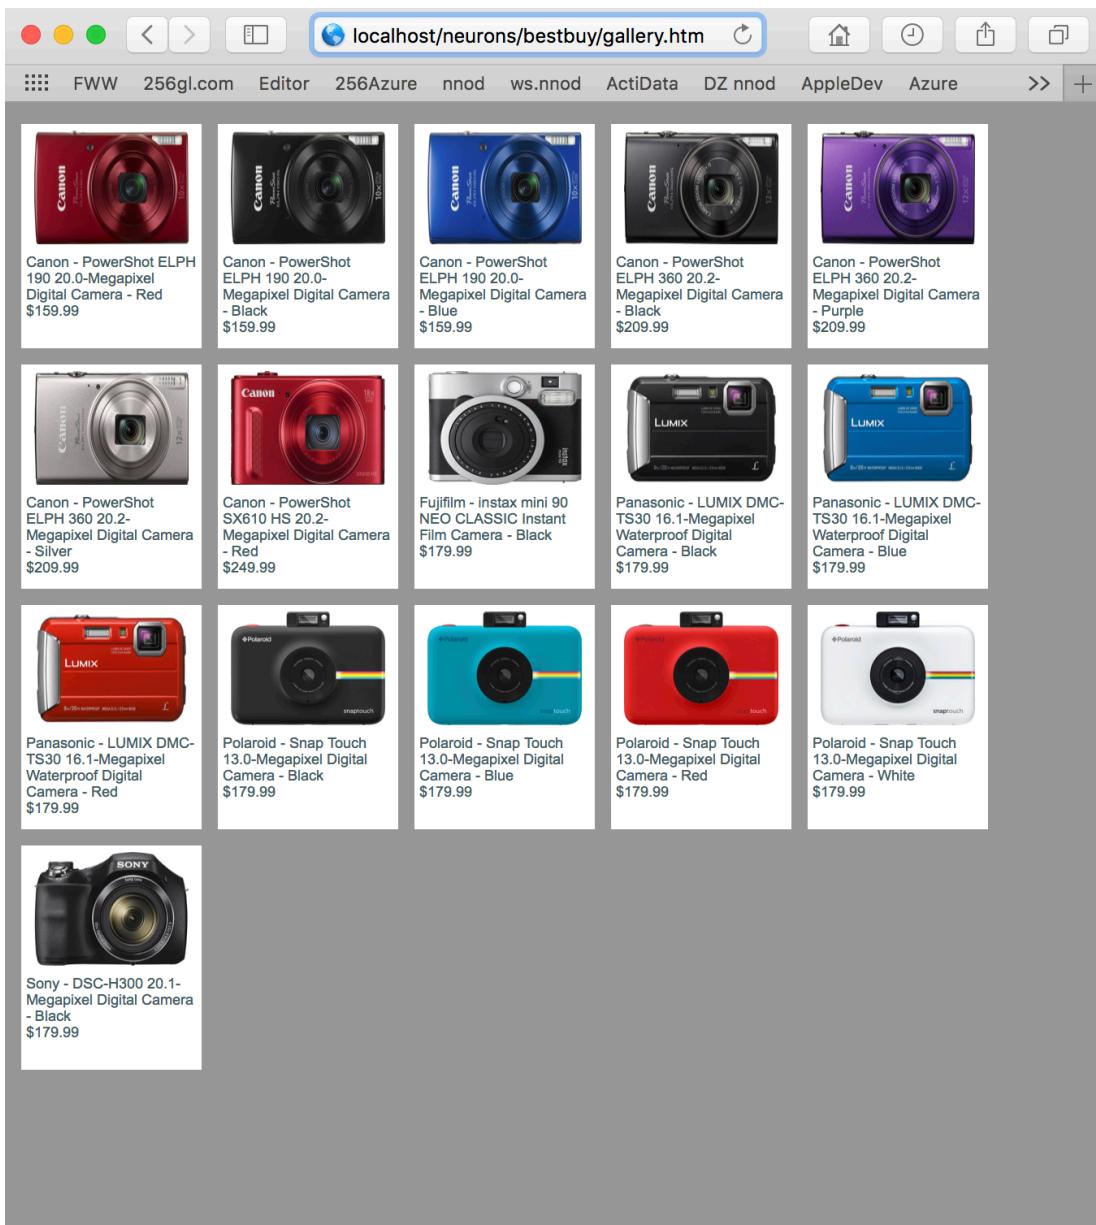

```

        "</td></tr></table></div> \n\n";
    }
    document.getElementById( "demo" ).innerHTML = x;
}
};

url = "https://api.bestbuy.com/v1/products\(customerReviewAverage%3E=4&regularPrice%3E150&regularPrice%3C250&\(categoryPath.id=abcat0401000\)\)?apiKey=xxxxxx&sort=name.asc&show=manufacturer,name,image,url,regularPrice&facet=regularPrice,50&pageSize=100&format=json";

xmlhttp.open( "GET", url, true);
xmlhttp.send();
</script>
</body>
</html>

```

Parameters in HTTP Request

BB API allows to send request only with certain relatively restricted set of parameters. Currently we can only request products defined by: Category, CustomerReview, Manufacturer, Color and price. The formal request to BB Database then can be build only with variety of these parameters.

We will use basic HTTP Get method:

<http://localhost/neurons/bestbuy/gallery.htm?color=silver&manufacturer=apple&customerReviewAverage=3&price=1500>

Our request page (gallery.htm) have basic arguments parser and few logical adjustments.

It is almost impossible in informal request define price as an exact number, so we will convert the price into the range and if no exact criteria provided, the price for request will be calculated as:

```
regularPrice_gt = price - Math.round(price / 4)
regularPrice_lt = price + Math.round(price / 4)

price >= regularPrice_gt && price <= regularPrice_lt
```

The whole arguments parsing for the page is following:

```
var api_key = "7ksBhjryZ5hxofJSEk2VB07u";
var baseURL = "https://api.bestbuy.com/v1/products";
var categoryId = get_arguments[ "categoryId" ];
if (categoryId === undefined) categoryId = "abcat0502000";

//      abcat0502000 - Laptops
//      abcat0501000 - Computers
//      abcat0401000 - Cameras
//      pcmcat209400050001 - phones
//      abcat0204000 - Hesad phones
//      pcmcat241600050001 - Home Audio
//      pcmcat254000050002 - Home Automation
//      pcmcat209000050006 - iPads
//      abcat0904000 - Ovens
//      abcat0901000 - Refrigerators
//      abcat0101000 - TVs
//      abcat0910000 - Washers
//      pcmcat310200050004 -Speakers

var customerReviewAverage = get_arguments[ "customerReviewAverage" ];
```

```

if (customerReviewAverage === undefined)
{
    customerReviewAverage = "";
}else
{
    customerReviewAverage = customerReviewAverage - 0.1
    customerReviewAverage = "&customerReviewAverage>=" + customerReviewAverage;
}
var manufacturer = get_arguments[ "manufacturer" ];
if (manufacturer === undefined)
{
    manufacturer = "";
}else
{
    manufacturer = "&manufacturer=" + manufacturer;
}
var color = get_arguments[ "color" ];
if (color === undefined)
{
    color = "";
}else
{
    color = "&color=" + color;
}
var regularPrice_gt = 0;
var regularPrice_lt = 100000;
var price = get_arguments[ "price" ];
if (price === undefined || price === "")
{
    price = "regularPrice>=" + regularPrice_gt +
            "&regularPrice<=" + regularPrice_lt;
}else
{
    regularPrice_gt = Math.round(price) - Math.round(price / 4);
    regularPrice_lt = Math.round(price) + Math.round(price / 4);
    price = "regularPrice>=" + regularPrice_gt +
            "&regularPrice<=" + regularPrice_lt;
}
var url = baseURL + "(" + price + customerReviewAverage + manufacturer + color +
"&(categoryPath.id=" + categoryId + "))" +
"?apiKey=" + api_key +
"&sort=name.asc&show=manufacturer,name,image,url,regularPrice&facet=regularPrice,
50&pageSize=100&format=json";

```

With this update we can now request different category of products and update search criteria.

Day 3

Domain of Definition, Map Informal Requests into Formal Queries

One of the most important step in ChatBot design is clear understanding of "Domain of a Function". Informal human request will be mapped into the formal query. The goal of our design is to map practically endless variety of informal request into the limited set of allowed parameters in query, which will result with limited number of items from the DataBase. In our case, Best Buy API limited by **Product**, **Stores**, **Categories** and **Recommendation** types of queries. Understanding of this limitation makes development significantly simpler and formal.

We will limit this basic ChatBot with **Product** only search but all possibilities to extend this solution with minimum modifications in the code could be done in next version.

Selected Feature: \$0.00

It is important for ChatBot not to pretend, but instead show its limit and capacity for user to avoid confusion. For this reason we combined the “content” layer together with control layer.

The new page combined three components: 1 - show available parameters for search, 2 - dialog and state of current interaction, 3 - content.

Screenshot of a web application interface titled "localhost" showing a grid of product cards. The left sidebar contains a navigation menu with categories like Laptops, Computers, Cameras, Phones, Head phones, Home Audio, Home Automation, iPads, Refrigerators, TVs, Washers, Speakers, and Ovens. Below the menu is a search bar and a price range selector from \$ to \$\$. A QR code is also present at the bottom left.

		Amazon - Echo (2nd generation) - Sandstone Fabric	\$99.99
		Amazon - Echo (2nd generation) - Silver	\$119.99

Day 4

Architecture, Integration and Multi Channel Chat

One of the goal of this project is to build not a single ChatBot, but smart communication channel, capable to interact with various data sources (in our case BB API) using different devices: PC with mouse and possible touch screen, smart phones, TV, smart home devices like Alexa. Various scenarios includes comprehensive interactive search from PC, relaxed shopping in front of TV, making shopping notes using Alexa or iPhone, and helping buyer inside the store with navigation and conversation with human expert:
